Lecture 11

Compiler II: Code Generation

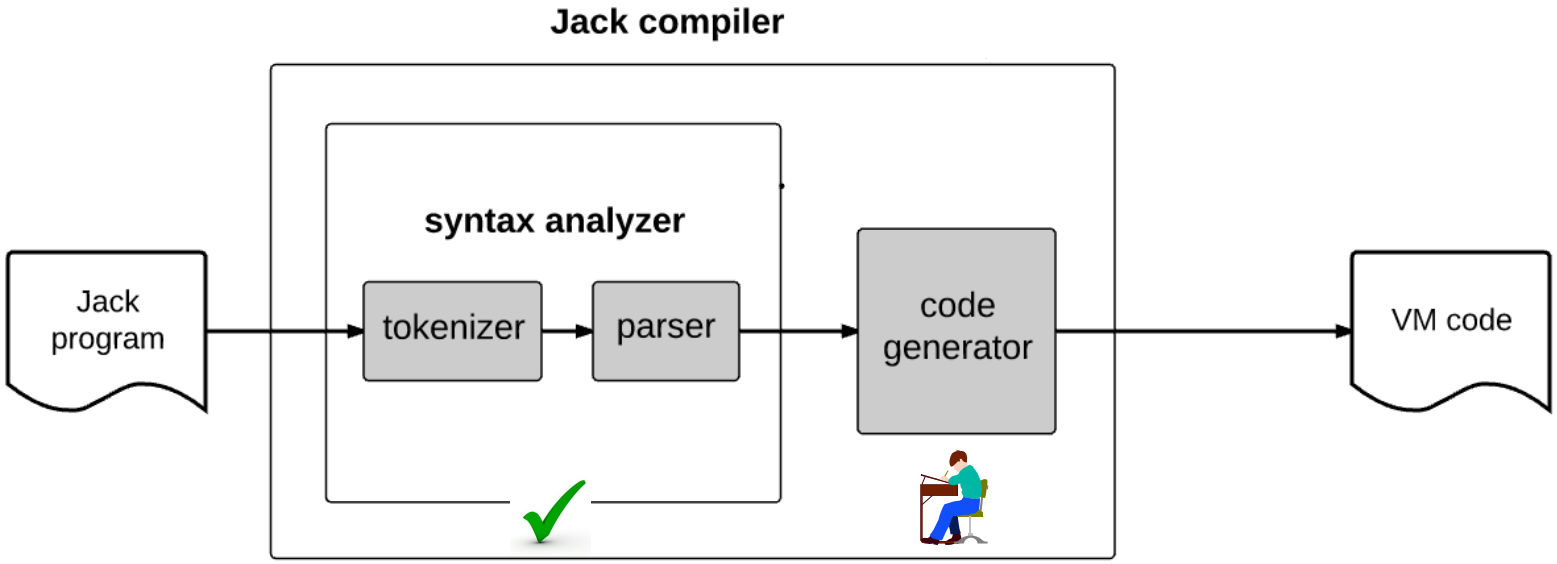
These slides support chapter 11 of the book

The Elements of Computing Systems

By Noam Nisan and Shimon Schocken

MIT Press, 2021

Compiler development roadmap



This lecture

Extending the syntax analyzer to a full-scale compiler.

Topics

Implementing a procedural programming language

- Variables
- Expressions
- Statements

Adding object-based programming features

- Objects
- Constructors
- Methods

Techniques

- Parsing (mostly done)
- Symbol tables
- Compilation engine
- Code generation.

Symbol table

Source code

```
class Point {
   field int x, y;
   static int pointCount;

   ...

   method int distance(Point other) {
      var int dx, dy;
      let dx = x - other.getx();
      let dy = y - other.gety();
      return Math.sqrt((dx*dx) + (dy*dy));
    }
    ...
}
```

Symbol table

Source code

```
class Point {
   field int x, y;
   static int pointCount;

   ...

   method int distance(Point other) {
      var int dx, dy;
      let dx = x - other.getx();
      let dy = y - other.gety();
      return Math.sqrt((dx*dx) + (dy*dy));
    }
    ...
}
```

Variable properties

name (identifier)

type (`int`, `char`, `boolean`, class name)

kind (`field`, `static`, `local`, `argument`)

scope (class level, subroutine level)

Symbol table

Source code

```
class Point {
   field int x, y;
   static int pointCount;

   ...

   method int distance(Point other) {
      var int dx, dy;
      let dx = x - other.getx();
      let dy = y - other.gety();
      return Math.sqrt((dx*dx) + (dy*dy));
    }
    ...
}
```

class-level symbol table

name	type	kind	#
x	int	this	0
y	int	this	1
pointCount	int	static	0

method-level symbol table

name	type	kind	#
this	Point	argument	0
other	Point	argument	1
dx	int	local	0
dy	int	local	1

`this` (`argument 0`) :
a system variable representing the object on which the method operates (discussed later in the lecture)

Variable properties

name (identifier)

type (`int`, `char`, `boolean`, class name)

kind (`field`, `static`, `local`, `argument`)

scope (class level, subroutine level)

The Jack compiler represents all the program's variables as entries in two symbol tables;

The tables are constructed and used during the compilation process.

Symbol table: Construction

Source code

class declaration

method declaration

```
class Point {
   field int x, y;
   static int pointCount;

   ...

   method int distance(Point other) {
      var int dx, dy;
      let dx = x - other.getx();
      let dy = y - other.gety();
      return Math.sqrt((dx*dx) + (dy*dy));
   }
   ...
}
```

class-level symbol table

name	type	kind	#
x	int	this	0
y	int	this	1
pointCount	int	static	0

method-level symbol table

name	type	kind	#
this	Point	argument	0
other	Point	argument	1
dx	int	local	0
dy	int	local	1

`this` (`argument 0`) :
a system variable representing the object on which the method operates (discussed later in the lecture)

Compiling a class declaration

The compiler creates a class-level sumbol table;

For each *field* and *static* variable found in the class declaration,
the compiler adds the variable to the symbol table as `this` *i* or as `static` *i*

Compiling a method declaration

The compiler creates a method-level sumbol table, and adds to it the entry <`this` *className* `argument 0`>;

For each *parameter* and *local* variable found in the method declaration,
the compiler adds the variable to the symbol table as `argument` *i* or as `local` *i*

The compiler generates the *i* values from running counters, one for each of the four memory segments.

Symbol table: Usage

Source code

class declaration

method declaration

```
class Point {
   field int x, y;
   static int pointCount;

   ...

   method int distance(Point other) {
      var int dx, dy;
      let dx = x - other.getx();
      let dy = y - other.gety();
      return Math.sqrt((dx*dx) + (dy*dy));
   }
   ...
}
```

class-level symbol table

name	type	kind	#
x	int	this	0
y	int	this	1
pointCount	int	static	0

method-level symbol table

name	type	kind	#
this	Point	argument	0
other	Point	argument	1
dx	int	local	0
dy	int	local	1

`this` (`argument 0`) :
a system variable representing the object on which the method operates (discussed later in the lecture)

Compiling statements

For each variable found in the statement:

The compiler looks up the variable in the method-level symbol table;

If found, the variable is replaced with its *segment i* reference;

Else, the compiler looks up the variable in the class-level symbol table;

If found, the variable is replaced with its *segment i* reference;

Else, the compiler throws a compilation error.

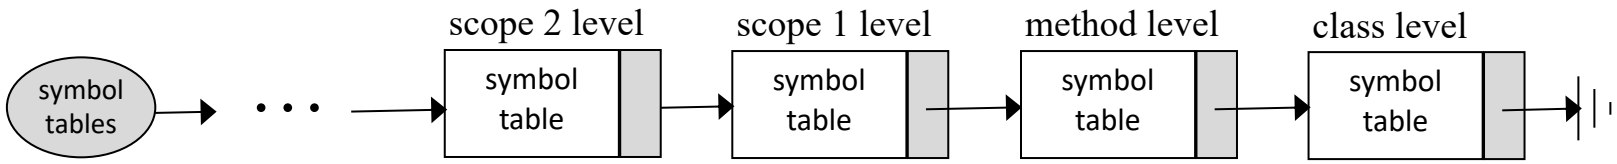
For example, `x + dx` is compiled into `push this 0`, `push local 0`, `add`.

Nested scoping

```
class foo {
   // class-level variable declarations
   method bar () {
      // method-level variable declarations
      ...
         {
            // scope-1-level variable declarations
            ...
               {
                  // scope-2-level variable declarations
                  ...
```

Some high-level languages (but not Jack) feature nested variable scoping of unlimited depth

Nested scoping can be handled using a linked list of symbol tables:



Variable lookup: The variable is looked up in the first table in the list: if not found, the next table is looked up, and so on.

Variable life cycles

Source code

```
class Point {
   field int x, y;
   static int pointCount;
   ...
   method int distance(Point other) {
      var int dx, dy;
      let dx = x - other.getx();
      let dy = y - other.gety();
      return Math.sqrt((dx*dx) + (dy*dy));
    }
    ...
}
```

Static variables: Persist throughout the program's execution

Field variables: Persist as long as the objects are not disposed

Local variables: Each time a subroutine starts running during runtime, it gets a fresh set of local variables; Each time a subroutine returns, its local variables are recycled

Argument variables: Same as local variables

Managing these variable life cycles is a major headache;

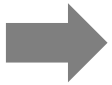
But… this is taken care of by the VM implementation (projects 7–8);

The compiler need not worry about it!

Lecture plan

Compilation

Handling variables



Handling expressions

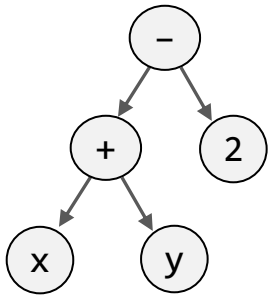
- Handling statements
- Handling objects
- Handling arrays

Compiling expressions

infix notation

```
x + y - 2
```

human
friendly



postfix notation

```
x y + 2 -
```

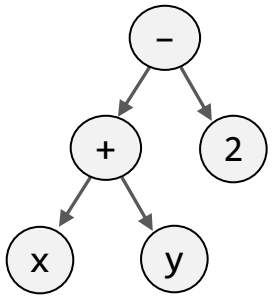
stack automata
friendly

Compiling expressions

source code

```
x + y - 2
```

parse



generate

VM code

```
// x + y - 2
push x
push y
add
push 2
sub
```

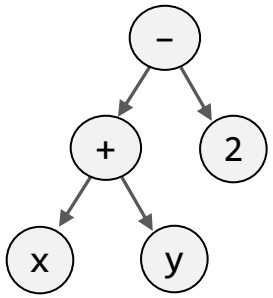
When executed during runtime, the generated code ends up leaving the value of the expression at the stack's top

Compiling expressions

source code

```
x + y - 2
```

parse



generate

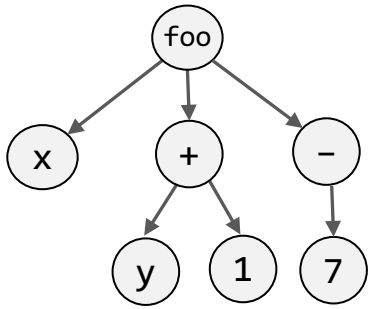
VM code

```
// x + y - 2
push x
push y
add
push 2
sub
```

another example

```
foo(x, y + 1, -7)
```

parse



generate

```
// foo(x, y + 1, -7)
push x
push y
push 1
add
push 7
neg
call foo 3
```

Needed:

A definition of "expression";

A general algorithm for compiling expressions.

Compiling expressions

Recursive algorithm for compling expressions:

compileExpression(*exp*):

if *exp* is *term*:
  compileTerm(*term*)

if *exp* is "$term_1$ op_1 $term_2$ op_2 $term_3$ op_3 ... $term_n$":
  compileTerm($term_1$)
  compileTerm($term_2$)
  output "op_1"
  compileTerm($term_3$)
  output "op_2"
  ...
  compileTerm($term_n$)
  output "op_{n-1}"

compileTerm(*term*):

if *term* is a constant *c*:
  output "push *c*"

if *term* is a variable *var*:
  output "push *var*"

if *term* is "*unaryOp term*":
  compileTerm(*term*)
  output "*unaryOp*"

if *term* is "*f* (exp_1, exp_2, ...)":
  compileExpression(exp_1)
  compileExpression(exp_2)
  ...
  compileExpression(exp_n)
  output "call *f* n"

if *term* is "(*exp*)":
  compileExpression(*exp*)

Generated code (examples)

```
// x + y – 2
push x
push y
add
push 2
sub
```

```
// foo(x, y + 1, -7)
push x
push y
push 1
add
push 7
neg
call foo 3
```

Jack grammar (subset):

expression: $term_1$ op_1 $term_2$ op_2 $term_3$ op_3 ... $term_n$

term: *constant* | *varName* | *unaryOp term* | *subroutineCall* | (*expression*)

subroutineCall: *f* ($expression_1$, $expression_2$, ... , $expression_n$)

Compiling expressions

Recursive algorithm for compling expressions:

compileExpression(*exp*):

if *exp* is *term*:
  compileTerm(*term*)

if *exp* is "$term_1$ op_1 $term_2$ op_2 $term_3$ op_3 ... $term_n$":
  compileTerm($term_1$)
  compileTerm($term_2$)
  output "op_1"
  compileTerm($term_3$)
  output "op_2"
  ...
  compileTerm($term_n$)
  output "op_{n-1}"

compileTerm(*term*):

if *term* is a constant *c*:
  output "push *c*"

if *term* is a variable *var*:
  output "push *var*"

if *term* is "*unaryOp term*":
  compileTerm(*term*)
  output "*unaryOp*"

if *term* is "*f* (exp_1, exp_2, ...)":
  compileExpression(exp_1)
  compileExpression(exp_2)
  ...
  compileExpression(exp_n)
  output "call *f* n"

if *term* is "(*exp*)":
  compileExpression(*exp*)

Generated code (examples)

```
// x + y – 2
push x
push y
add
push 2
sub
```

```
// foo(x, y + 1, -7)
push x
push y
push 1
add
push 7
neg
call foo 3
```

Notes:

The complete algorithm must implement the complete grammar of Jack expressions;

The complete algorithm must generate VM code in which variables are represented as `local` *i*, `argument` *i*, etc. (instead of `x`, `y`, etc.)

Lecture plan

Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ➡ Handling statements
- Handling objects
- Handling arrays

Lecture plan

Compilation

✓ Handling variables

✓ Handling expressions

➡ Handling statements

- `let`
- `return`
- `do`
- `if`
- `while`

We'll describe how to compile each statement, and outline a compilation routine that handles it.

Lecture plan

Compilation

✓ Handling variables

✓ Handling expressions

- Handling statements

`let`
`return`
`do`
`if`
`while`

We'll describe how to compile each statement, and outline a compilation routine that handles it.

Compiling `let`

source code (Jack)

```
...
let varName = expression;
...
```

VM code (generated by `compileLet`)

```
...
VM code generated by compileExpression
pop varName
...
```

When the VM code generated by `compileExpression` will execute during runtime, it will end up leaving the expression's value at the stack's top.

The subsequent `pop` will then store this value in the segment entry.

Compiling `let`

source code (Jack)

```
...
let varName = expression;
...
```

compiler

VM code (generated by `compileLet`)

```
...
VM code generated by compileExpression
pop varName
...
```

example

```
let v = g + r2;
```

compiler

```
push g
push r2
add
pop v
```

1. first three commands are generated by `compileExpression`
2. Instead of symbolic variable names, the generated VM code uses segment entries.

General compilation routine:

`compileLet`:

`compileExpression`

output "`pop static` / `this` / `argument` / `local` *i* "

Lecture plan

Compilation

- Handling variables
- Handling expressions
- Handling statements

```
let
return
do
if
while
```

Compiling `return` *expression*

source code

```
...
return expression;
...
```

VM code (generated by `compileReturn`)

```
...
VM code generated by compileExpression
return
...
```

When the VM code generated by `compileExpression` will execute during runtime, it will end up leaving the expression's value at the stack's top;

The VM implementation of the subsequent `return` command will place the return value at the top of caller's working stack.

General compilation routine:

```
compileReturn:
    compileExpression
    output "return"
```

Compiling `return`

source code

```
...
return;
...
```

compiler

VM code (generated by `compileReturn`)

```
...
push constant 0
return
...
```

When compiling a `return` Jack statement with no return value, the `compileReturn` routine generates code that pushes a dummy value onto the stack;

The dummy value will be tossed away by the compiled code of the caller (discussed next).

General compilation routine:

`compileReturn`:

output "`push constant 0`"

output "`return`"

Conventions: (1) A Jack subroutine must end with a `return` / `return` *value* statement

(2) The compiled code of a subroutine always returns a value (even if it's `void`).

Lecture plan

Compilation

- Handling variables
- Handling expressions
- Handling statements
  - `let`
  - `return`
  - `do`
  - `if`
  - `while`

Compiling do

source code (Jack)

```
...
do subroutineName(exp1, exp2, ...)
...
```

compiler

VM code (generated by `compileDo`)

```
...
VM code generated by compileExpression
pop temp 0
...
```

Used to call a function or a method for its effect, ignoring the returned value

The pop gets rid of the return value.

example

```
do Output.printInt(7);
```

compiler

```
push constant 7
call Output.printInt 1
pop temp 0
```

first two commands are generated by `compileExpression`

General compilation routine:

`compileDo`:

`compileExpression`

output "`pop temp 0`"

Explanation:

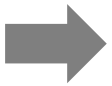
We compile `do` *subroutineName*`(…)` statements as if they where `do` *expression* statements;

The `compileExpression` routine knows how to handle method calls.

Lecture plan

Compilation

- Handling variables
- Handling expressions
- Handling statements



`let`
`return`
`do`
`if`
`while`

Compiling `if`

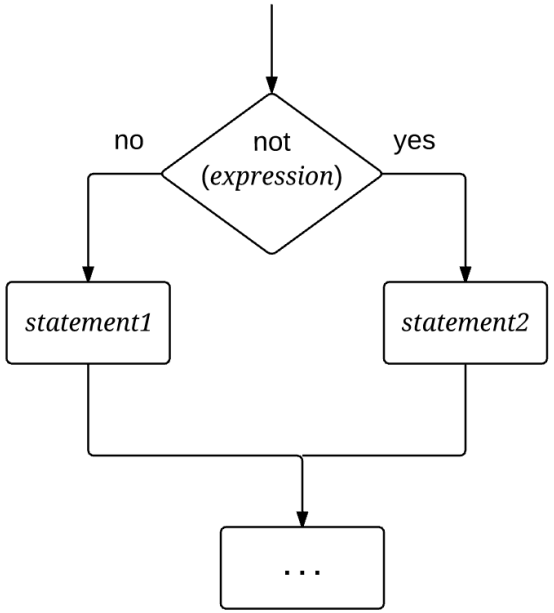
source code

```
if (expression)
    {statements1}
else
    {statements2}
...
```

compiler

VM code (generated by `compileIf`)

```
    VM code generated by compileExpression
    not
    if-goto L1
    VM code generated by compileStatements
    goto L2
label L1
    VM code generated by compileStatements
label L2
    ...
```



`compileStatements`: a simple compilation routine that uses a loop to compile a sequence of zero or more `let`, `return`, `do`, `if`, `while` statements

Compiling `if`

source code

```
if ( expression )
    { statements1 }
else
    { statements2 }
...
```

compiler

VM code (generated by `compileIf`)

```
    VM code generated by compileExpression
    not
    if-goto L1
    VM code generated by compileStatements
    goto L2
label L1
    VM code generated by compileStatements
label L2
    ...
```

example

```
if (x < 0) {
   let y = 0;
} else {
   let y = 1;
}
...
```

compiler

```
    push x
    push 0
    lt
    not
if-goto L1
    push 0
    pop y
    goto L2
label l1
    push 1
    pop y
label L2
    ...
```

Compiling `if`

source code

```
if (expression)
    {statements1}
else
    {statements2}
...
```

compiler

VM code (generated by `compileIf`)

```
    VM code generated by compileExpression
    not
    if-goto L1
    VM code generated by compileStatements
    goto L2
label L1
    VM code generated by compileStatements
label L2
    ...
```

General compilation routine:

`compileIf`:

- `compileExpression`
- output "`not`"
- generate a unique label `L1`, and output "`if-goto L1`"
- `compileStatements`
- generate a unique label `L2`, and output "`goto L2`"
- output "`label L1`"
- `compileStatements`
- output "`label L2`"

Compiling `while`

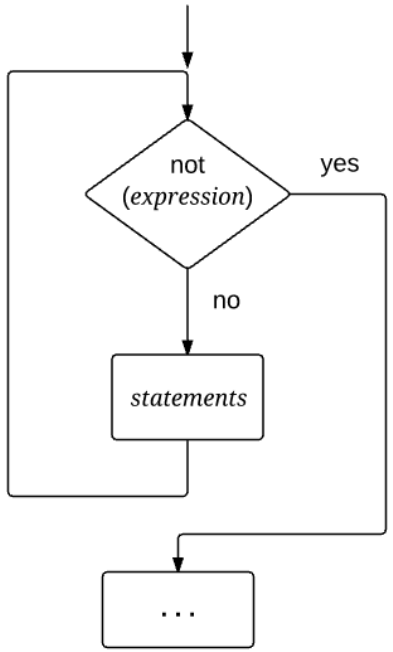
source code

```
while ( expression )
    { statements }
...
```

compiler

VM code (generated by `compileWhile`)

```
label L1
   VM code generated by compileExpression
   not
   if-goto L2
   VM code generated by compileStatements
   goto L1
label L2
   ...
```



Compiling `while`

source code

```
while ( expression )
    { statements }
...
```

compiler

VM code (generated by `compileWhile`)

```
label L1
  VM code generated by compileExpression
  not
  if-goto L2
  VM code generated by compileStatements
  goto L1
label L2
  ...
```

example

```
while (g = 0) {
   let x = x + 1;
}
...
```

compiler

```
label L1
  push g
  push 0
  eq
  not
  if-goto L2
  push x
  push 1
  add
  pop x
  goto L1
label L2
  ...
```

(pseudo code)

Compiling `while`

source code

```
while ( expression )
    { statements }
...
```

VM code (generated by `compileWhile`)

```
label L1
   VM code generated by compileExpression
   not
   if-goto L2
   VM code generated by compileStatements
   goto L1
label L2
   ...
```

General compilation routine:

`compileWhile`:

- generate the unique label `L1`, and output "`label L1`"
- `compileExpression`
- output "`not`"
- generate the unique label `L2`, and output "`if-goto L2`"
- `compileStatements`
- output "`goto L1`"
- output "`label L2`"

Lecture plan

Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements

We have what it takes to write a compiler for a procedural programming language!

- Handling objects
- Handling arrays

Lecture plan

Compilation

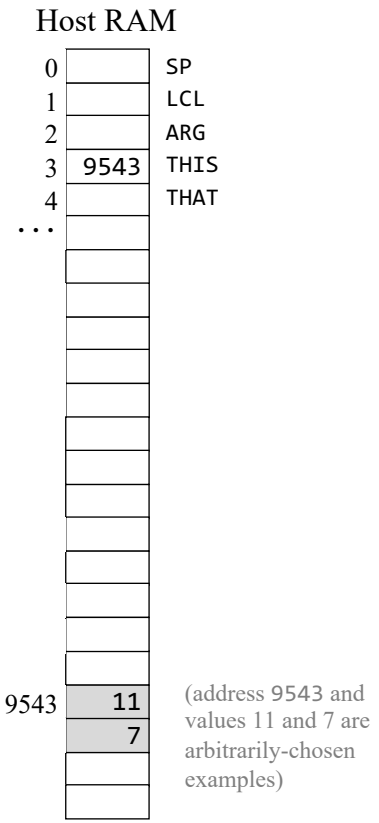
- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- Handling objects
  - ➡ Structures
    - Constructing objects
    - Manipulating objects
- Handling arrays

“Structures”

In the C language, a *structure* is a composite data type, consisting of several *fields*;

In the example shown here, `THIS` points at a two-field structure;

How can we create and manipulate structures using the VM language?



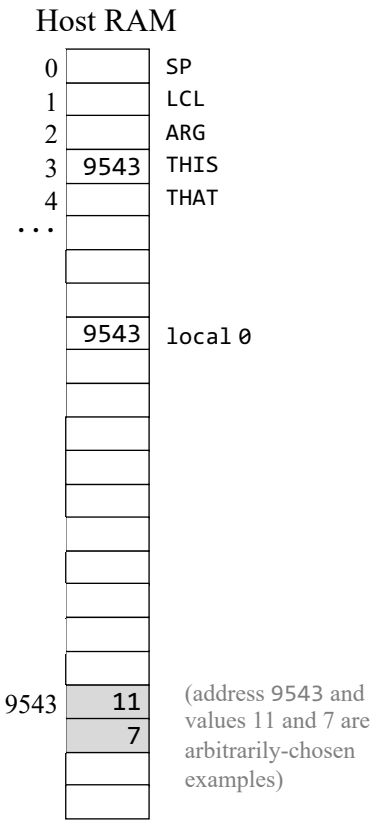
“Structures”

Creating a structure:

```
// Creates a 2-word structure, initializes it, and makes local 0 refer to it
push constant 2
call Memory.alloc 1
pop pointer 0    // pop THIS

push constant 11
pop this 0
push constant 7
pop this 1

push pointer 0    // push THIS
pop local 0
```



Explanation

`Memory.alloc`(*n*): Calls a memory allocation OS function.
`alloc` finds a memory block of size *n* words, and returns (pushes onto the stack) its base address;

`pop pointer 0`: Pops the base address of the new structure into `THIS`;
Result: Subsequent `this` *i* references will map on RAM addresses `THIS` + *i*

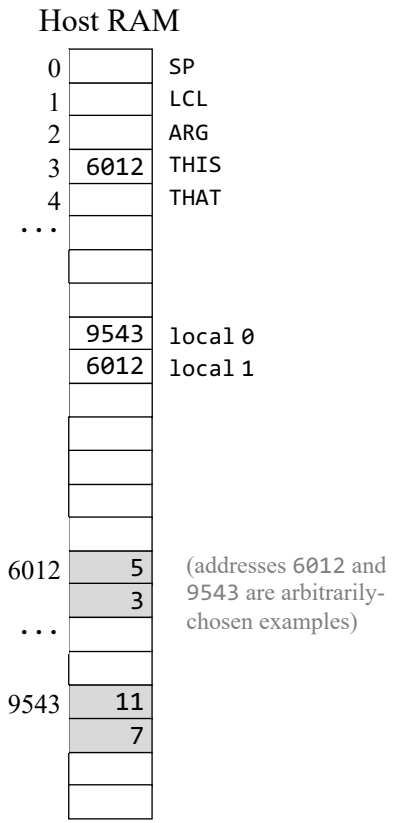
Last two commands: Make `local 0` point to the new structure.

“Structures”

Manipulating a structure:

```
// Creates two structures and makes local 0 and local 1 point to them
// (code omitted)
...

// Example of manipulating a structure:
// Sets the fields of p2 to 5 and 3
push local 1
pop pointer 0     // THIS = base address of the target structure
push constant 5
pop this 0
push constant 3
pop this 1
```



Note

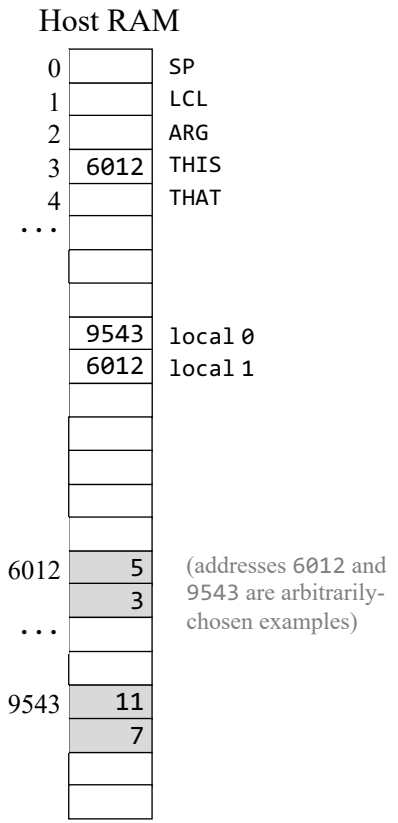
Using this technique, we can get / set the fields of any given structure.

“Structures”

Manipulating a structure:

```
// Creates two structures and makes local 0 and local 1 point to them
// (code omitted)
...

// Example of manipulating a structure:
// Sets the fields of p2 to 5 and 3
push local 1
pop pointer 0     // THIS = base address of the target structure
push constant 5
pop this 0
push constant 3
pop this 1
```



From structures to objects

“Objects” are well-dressed structures;

The big step from C to C++ is that C++ compilers allow creating and manipulating objects using a dedictaed, object-oriented terminology;

The Jack language and compiler feature such OOP cabailities (next).

Lecture plan

Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- Handling objects
  - Structures
  - → Compiling objects construction
  - Compiling objects manipulations
- Handling arrays

Compiling constructors

Source code

```
class Foo {
   ...
   function void bar () {
      var Point p1;
      ...
      // Creates a new Point object
      let p1 = Point.new(2,3);
      ...
```

(such constructor calls can appear in any subroutine, in any class)

Caller: Creates an object, by calling a constructor

Compiling constructors

Source code

```
class Foo {
   ...
   function void bar () {
      var Point p1;
      ...
      // Creates a new Point object
      let p1 = Point.new(2,3);
      ...
```

(such constructor calls can appear in any subroutine, in any class)

compiler

VM code

```
...
// let p1 = Point.new(2,3);
push constant 2
push constant 3
call Point.new 2
pop local 0
...
```

Observations

- There's nothing special about compiling *constructor calls*; We handle them as if they were regular subroutine calls.
- The calls are serviced by the compiled constructors.

Compiling constructors

Source code

```
...
// Creates a new Point object
let p1 = Point.new(2,3);
```

Caller: Creates an object, by calling a constructor

```
/** Represents a Point. */
class Point {
   field int x, y;
   static int pointCount;
   ...

   /** Constructs a new point. */
   constructor Point new(int ax, int ay) {
      let x = ax;
      let y = ay;
      let pointCount = pointCount + 1;
      return this;  //// required in Jack constructors
   }
   ...
```

Callee: Does the object construction

Typical client-server, OOP, object construction idiom;

What makes the magic work? The compiled constructor's code.

Compiling constructors

Source code

```
...
// Creates a new Point object
let p1 = Point.new(2,3);
```

```
/** Represents a Point. */
class Point {
   field int x, y;
   static int pointCount;
   ...

   /** Constructs a new point. */
   constructor Point new(int ax, int ay) {
      let x = ax;
      let y = ay;
      let pointCount = pointCount + 1;
      return this;  //// required in Jack constructors
   }
   ...
```

VM code (created by `compileClass`)

Compiling constructors

Source code

```
...
// Creates a new Point object
let p1 = Point.new(2,3);
```

```
/** Represents a Point. */
class Point {
   field int x, y;
   static int pointCount;
   ...

   /** Constructs a new point. */
   constructor Point new(int ax, int ay) {
      let x = ax;
      let y = ay;
      let pointCount = pointCount + 1;
      return this;  //// required in Jack constructors
   }
   ...
```

compiler

VM code (created by `compileClass`)

```
// class Point {
//    field int x, y;
//    static int pointCount;
//// compileClass builds the class-level symbol table
```

class-level symbol table

name	type	kind	#
x	int	this	0
y	int	this	1
pointCount	int	static	0

Compiling constructors

Source code

```
...
// Creates a new Point object
let p1 = Point.new(2,3);
```

```
/** Represents a Point. */
class Point {
   field int x, y;
   static int pointCount;
   ...

   /** Constructs a new point. */
   constructor Point new(int ax, int ay) {
      let x = ax;
      let y = ay;
      let pointCount = pointCount + 1;
      return this; //// required in Jack constructors
   }
   ...
```

compiler

VM code (created by `compileClass`)

```
// class Point {
//    field int x, y;
//    static int pointCount;
//// compileClass builds the class-level symbol table
// constructor Point new(int ax, int ay);
//// compileSubroutine builds the subroutine's symbol table, and notes that
//// it is handling a constructor. It generates VM code that declares a VM function,
//// allocates memory for the new object, and sets THIS to its base address:
function Point.new 0
   push constant 2
   call Memory.alloc 1
   pop pointer 0
```

class-level symbol table

name	type	kind	#
x	int	this	0
y	int	this	1
pointCount	int	static	0

constructor-level symbol table

```
...
// Creates a new Point object
let p1 = Point.new(2,3);
```

```
/** Represents a Point. */
class Point {
   field int x, y;
   static int pointCount;
   ...

   /** Constructs a new point. */
   constructor Point new(int ax, int ay) {
      let x = ax;
      let y = ay;
      let pointCount = pointCount + 1;
      return this;  //// required in Jack constructors
   }
   ...
```

compiler

VM code (created by `compileClass`)

```
// class Point {
//    field int x, y;
//    static int pointCount;
//// compileClass builds the class-level symbol table

// constructor Point new(int ax, int ay);
//// compileSubroutine builds the subroutine's symbol table, and notes that
//// it is handling a constructor. It generates VM code that declares a VM function,
//// allocates memory for the new object, and sets THIS to its base address:
function Point.new 0
   push constant 2
   call Memory.alloc 1
   pop pointer 0
   //// CompileStatements handles the constructor's body
   // let x = ax;
   push argument 0
   pop this 0

   ...

   // return this;
   push pointer 0
   return
```

class-level symbol table

name	type	kind	#
x	int	this	0
y	int	this	1
pointCount	int	static	0

constructor-level symbol table

name	type	kind	#
ax	int	argument	0
ay	int	argument	1

Compiling constructors

Source code

```
...
// Creates a new Point object
let p1 = Point.new(2,3);
```

```
/** Represents a Point. */
class Point {
   field int x, y;
   static int pointCount;
   ...

   /** Constructs a new point. */
   constructor Point new(int ax, int ay) {
      let x = ax;
      let y = ay;
      let pointCount = pointCount + 1;
      return this;  //// required in Jack constructors
   }
   ...
```

compiler

VM code (created by `compileClass`)

```
// class Point {
//    field int x, y;
//    static int pointCount;
//// compileClass builds the class-level symbol table
// constructor Point new(int ax, int ay);
//// compileSubroutine builds the subroutine's symbol table, and notes that
//// it is handling a constructor. It generates VM code that declares a VM function,
//// allocates memory for the new object, and sets THIS to its base address:
function Point.new 0
   push constant 2
   call Memory.alloc 1
   pop pointer 0
   //// CompileStatements handles the constructor's body
  // let x = ax;
   push argument 0
   pop this 0
   ...
   // return this;
   push pointer 0
   return
```

C++, Java, Python, ...

In Jack, every constructor must end with the explicit statement `return this;`

All OOP compilers do the same thing, implicitly:

Before terminating the compiled constructor code, they inject low-level code that returns the address of the newly consctructed object; That's how `p1` (in this example) ends up pointing at the new object.

Lecture plan

Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- Handling objects
  - Structures
  - Compiling objects construction
  - ➡ Compiling objects manipulations
- Handling arrays

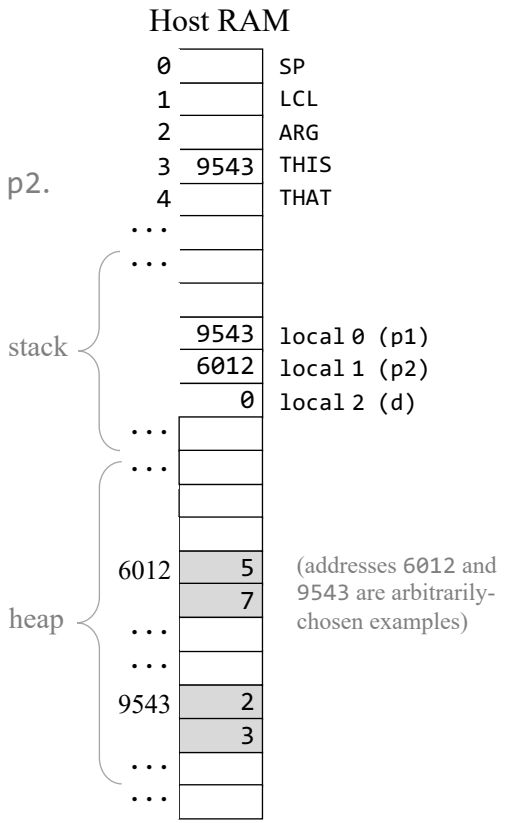
Compiling methods

source code

```
...
let d = p1.distance(p2)
...
```

```
/** Represents a Point. */
class Point {
  field int x, y;
  static int pointCount;
  ...
  /** Distance from this to the other point */
  method int distance(Point other) {
    var int dx, dy;
    let dx = x - other.getx();
    let dy = y - other.gety();
    return Math.sqrt((dx*dx) +
                     (dy*dy));
  }
  ...
}
```

We assume that the caller has already declared the local variables `p1`, `p2`, `d`, and constructed the objects `p1` and `p2`.



Compiling methods

source code

```
...
let d = p1.distance(p2)
...
```

Caller: "Applies a method to an object"

```
/** Represents a Point. */
class Point {
  field int x, y;
  static int pointCount;
  ...
  /** Distance from this to the other point */
  method int distance(Point other) {
    var int dx, dy;
    let dx = x - other.getx();
    let dy = y - other.gety();
    return Math.sqrt((dx*dx) +
                     (dy*dy));
  }
  ...
}
```

Callee: "Operates on the target object"

Typical client-server, OOP, object manipulation idioms;

What makes the magic happen? The compiler (next).

Compiling methods

source code

```
...
let d = p1.distance(p2)
...
```

compiler

VM code

```
...
push local 0
push local 1
call Point.distance 2
pop local 2
...
```

name	type	kind	#
p1	Point	local	0
p2	Point	local	1
d	int	local	2

caller's symbol table

```
/** Represents a Point. */
class Point {
  field int x, y;
  static int pointCount;
  ...
  /** Distance from this to the other point */
  method int distance(Point other) {
    var int dx, dy;
    let dx = x - other.getx();
    let dy = y - other.gety();
    return Math.sqrt((dx*dx) +
                     (dy*dy));
  }
  ...
}
```

When compiling a *method call*:

The compiler generates code that passes the target object as the *first argument* for the called method

This is the key compilation trick that facilitates the OO "object first" method calling idiom:

objName.*methodName*(*args*)

Compiling methods

source code

```
...
let d = p1.distance(p2)
...
```

Lecture plan

Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- ✓ Handling objects
- Handling arrays

Lecture plan

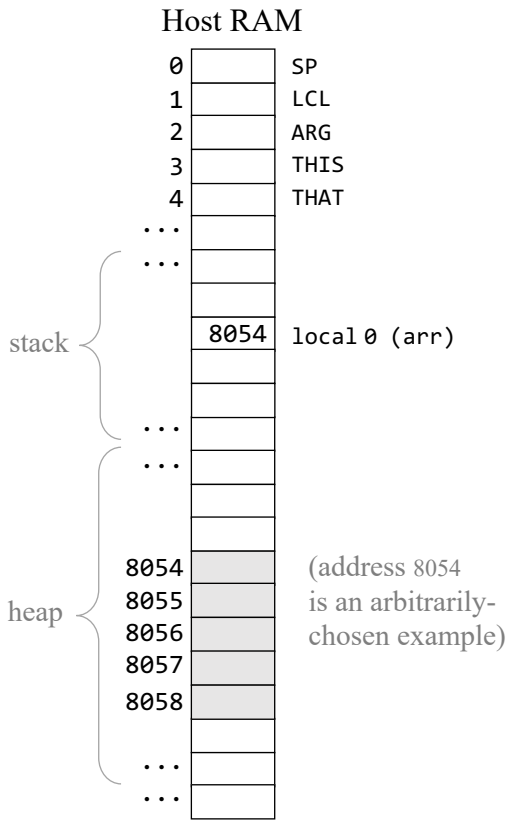
Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- ✓ Handling objects
- ➡ Handling arrays
  - Creating arrays
  - Manipulating arrays

Compiling array construction

Source code

```
// Can appear in any class/subroutine:
method foo() {
   // Declares an array variable:
   var Array arr;
   ...
   // Constructs the array:
   let arr = Array.new(5);
   ...
```



Jack conventions:

Arrays are instances of the OS class `Array`

To construct an array, we call `Array.new`

(The `Array` class will be implemented later in the course, when we'll build the OS).

Compiling array construction

Source code

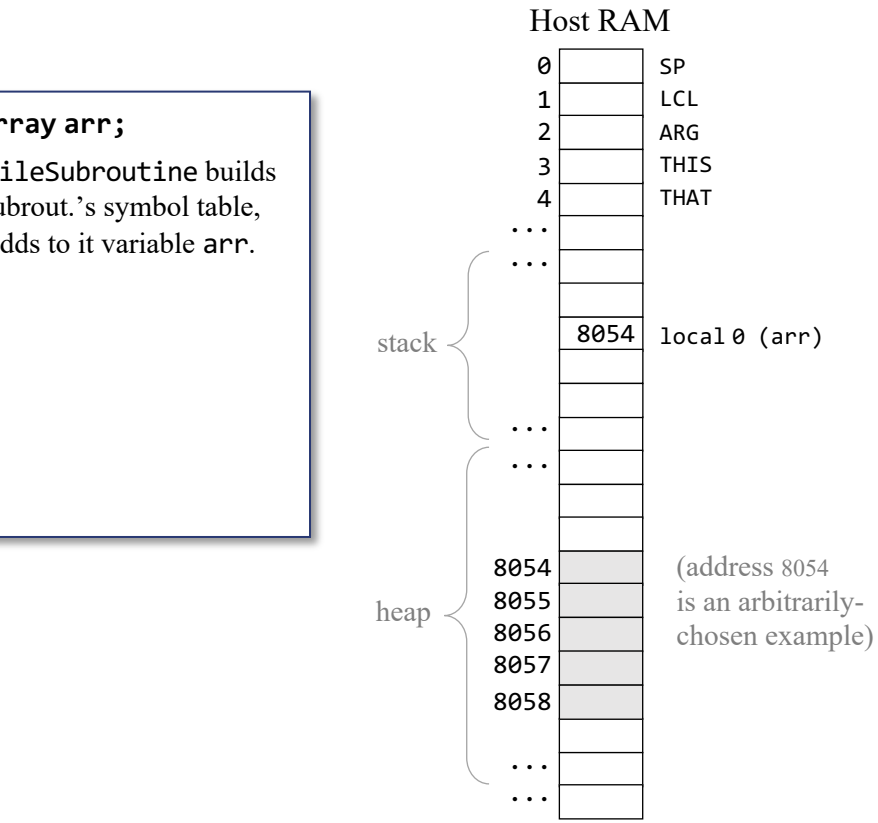
```
// Can appear in any class/subroutine:
method foo() {
   // Declares an array variable:
   var Array arr;
   ...
   // Constructs the array:
   let arr = Array.new(5);
   ...
```

compile

VM code

```
// var Array arr;
//// compileSubroutine builds
//// the subrout.'s symbol table,
//// and adds to it variable arr.
```

name	type	kind	#
arr	Array	local	0



Compiling array construction

Source code

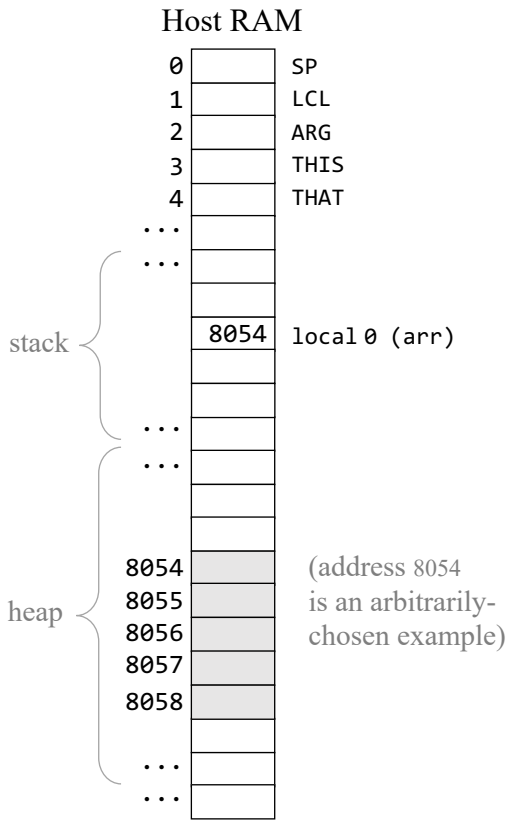
```
// Can appear in any class/subroutine:
method foo() {
  // Declares an array variable:
  var Array arr;
  ...
  // Constructs the array:
  let arr = Array.new(5);
  ...
```

compile

VM code

```
// var Array arr;
//// compileSubroutine builds
//// the subrout.'s symbol table,
//// and adds to it variable arr.
...
// let arr = Array.new(5);
push constant 5
call Array.new 1
pop local 0
...
```

name	type	kind	#
arr	Array	local	0



Compiling array construction:

We simply compile the `let` statement

(same as with calling an object constructor)

Lecture plan

Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- ✓ Handling objects
- Handling arrays
  - ✓ Creating arrays
  - ➡ Manipulating arrays

Accessing array elements

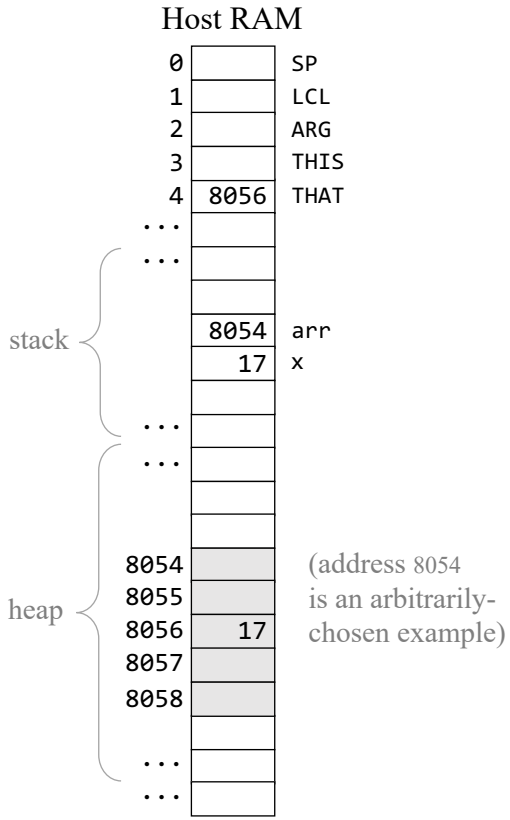
Examples

```
// let arr[2] = x
push arr
push 2
add
pop pointer 1
push x
pop that 0
```

Sets THAT to the address of the target array element

```
// let x = arr[2]
push arr
push 2
add
pop pointer 1
push that 0
pop x
```

same



Compiling array access

source code

```
let arr[i] = exp
```

compiler

VM code (generated by `compileLet`)

```
push arr
push i
add
pop pointer 1    // THAT = arr + 2
push exp
pop that 0
```

Generalizing:

`compileLet`: (`let` *varName*`[`*expression*`]` `=` *expression*`;`)

output "`push` *varName*"

`call compileExpression`

output "`add`"

output "`pop pointer 1`"

call `compileExpression`

output "`pop that 0`"

Compiling array access

source code (example)

```
let a[i] = b[j]
```

compiler

VM code (generated by `compileLet`)

```
push a
push i
add
pop pointer 1
// Now handle the right hand side
push b
push j
add
pop pointer 1
...
```

crash!

Generalizing:

`compileLet`: (`let` *varName*`[`*expression*`]` `=` *expression*`;`)

- output "`push` *varName*"
- `call compileExpression`
- output "`add`"
- output "`pop pointer 1`"
- call `compileExpression`
- output "`pop that 0`"

Compiling array access

source code (example)

```
let a[i] = b[j]
```

compiler

VM code (generated by `compileLet`)

```
push a
push i
add
pop pointer 1
// Now handle the right hand side
push b
push j
add
pop pointer 1
...
```

crash!

Generalizing:

~~`compileLet`: (`let` *varName*`[`*expression*`]` `=` *expression*`;`)~~

~~output "`push` *varName*"~~

~~`call compileExpression`~~

~~output "`add`"~~

~~output "`pop pointer 1`"~~

~~call `compileExpression`~~

~~output "`pop that 0`"~~

Compiling array access

source code (example)

```
let a[i] = b[j]
```

compiler

VM code (generated by `compileLet`)

```
push a
push i
add
push b
push j
add
pop pointer 1   // THAT = address of b[j]
push that 0     // stack top = b[j]
pop temp 0      // temp 0 = b[j]
pop pointer 1   // THAT = address of a[i]
push temp 0     // stack top = b[j]
pop that 0      // a[i] = b[j]
```

`compileLet`: (`let` *varName*`[`*expression*`]` `=` *expression*`;`)

// (both expressions can contain array elements, of any depth)
output "`push` *varName*"
call `compileExpression`
output "`add`"
call `compileExpression`
output "`pop pointer 1`"
...
output "`pop that 0`"

6 fixed push/pop commands at the bottom of the VM code shown above

What about compiling, say,

`let a[a[i]] = a[b[a[b[j]]]]` ?

No problem...

Lecture plan

Compilation

- ✓ Handling objects
- ✓ Handling arrays

Implementation

- ➡ Standard mapping
- Proposed design
- Project 11

Standard mapping

So far we described:

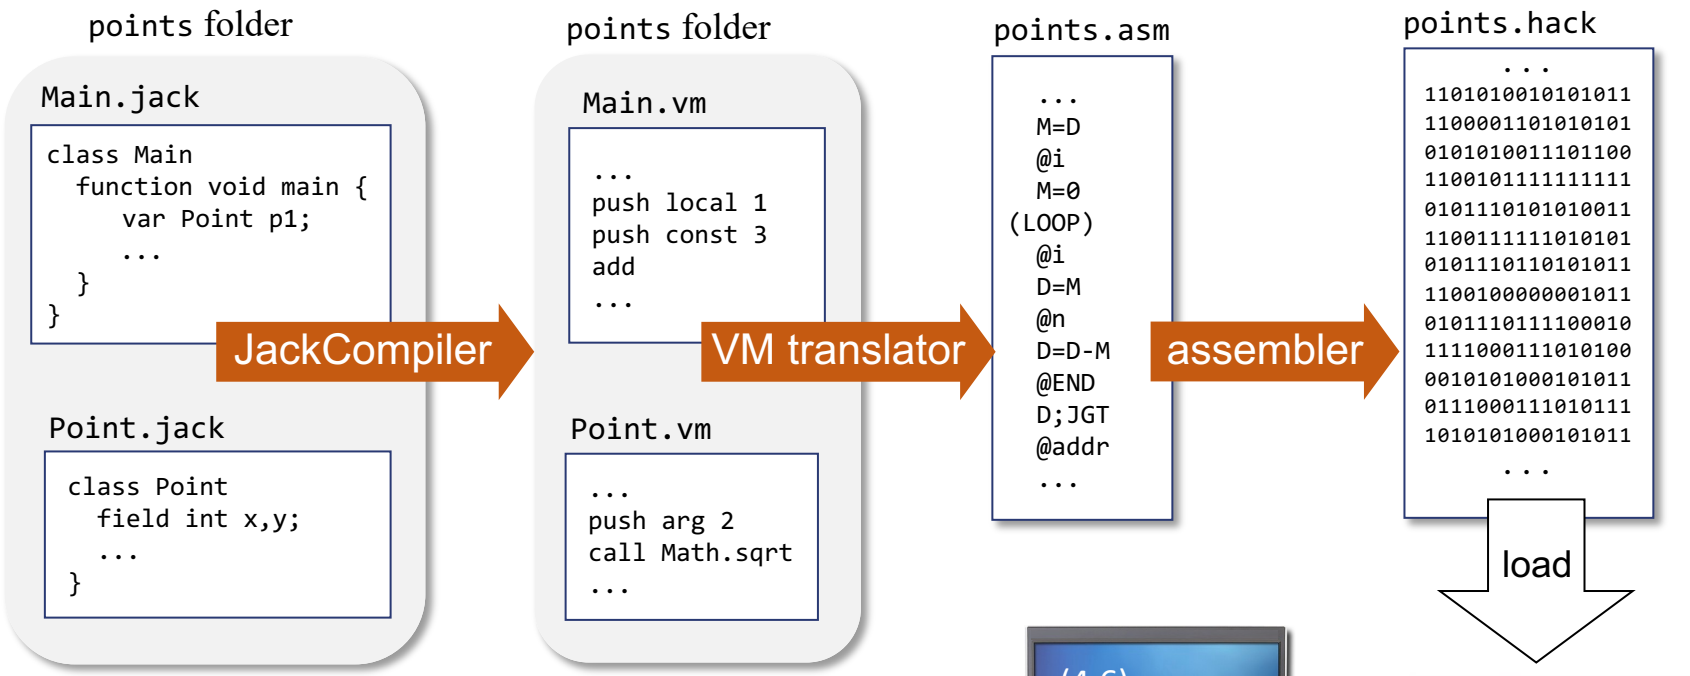
- General compilation techniques
- Compiling Jack code

We now turn to describe:

How to generate code for the the specific VM language and OS of the Hack computer

(There will be some repetition of things already described).

The big picture



A Jack program is a collection of one or more class files, in same folder (here, named `points`)

Each class file *ClassName*`.jack` is *compiled separately* into the file *ClassName*`.vm`

Subroutines (implementation notes)

Foo.jack

```
class Foo {

  constructor Foo new(int x) {}

  method void bar(int x) {}

  function int baz(int x) {}
}
```

JackCompiler

Foo.vm

```
function Foo.new
  ...
function Foo.bar
  ...
function Foo.baz
  ...
```

Each subroutine (constructor, function, method) *subName* in a file *ClassName*`.jack`
is compiled into a VM function named *ClassName*`.`*subName*

Constants (implementation notes)

The Jack language has four constants

`true` is represented in VM code as `constant 1`, followed by `neg`

`false` is represented in VM code as `constant 0`

`null` is represented in VM code as `constant 0`

`this` is represented in VM code as `pointer 0`

Variables (implementation notes)

Local variables

Are mapped on `local 0`, `local 1`, `local 2`, ...

Argument variables

Are mapped on `argument 0`, `argument 1`, `argument 2`, ...

Static variables

Are mapped on `static 0`, `static 1`, `static 2`, ...

Field variables

Are mapped on `this 0`, `this 1`, `this 2`, ...

Arrays (implementation notes)

Access to array element `arr[i]`

Is implemented by generating VM code that realizes:

set `pointer 1` to `arr + i`

`push` / `pop that 0`

Implementation tip: There is never a need use `that` *i* for *i* greater than 0.

Subroutine calls (implementation notes)

(Suppose that we are compiling the file *ClassName*`.jack`)

Compiling a constructor call or a function call *subName*(*exp*$_1$, *exp*$_2$, ..., *exp*$_n$)

The generated VM code pushes the expressions *exp*$_1$, *exp*$_2$, ..., *exp*$_n$ onto the stack, followed by the command `call` *ClassName*`.`*subName* *n*

Compiling a method call *obj*`.`*subName*(*exp*$_1$, *exp*$_2$, ..., *exp*$_n$)

The generated VM code pushes *obj* and then *exp*$_1$, *exp*$_2$, ..., *exp*$_n$ onto the stack, followed by the command `call` *ClassName*`.`*subName* *n*+1

If the called subroutine is *void*:

Just after the call, the generated VM code gets rid of the return value using the command `pop temp 0`

Subroutines (implementation notes)

When compiling a Jack method:

- The first entry in the method's symbol table must be a variable named `this` whose *type* is the name of the class to which the method belongs, *kind* is `argument`, and *index is* `0`
- The generated VM code starts by setting `pointer 0` to `argument 0`

When compiling a Jack constructor:

- The generated VM code starts by:

  Calling the OS function `Memory.alloc` *n*, where *n* is the number of fields in the class

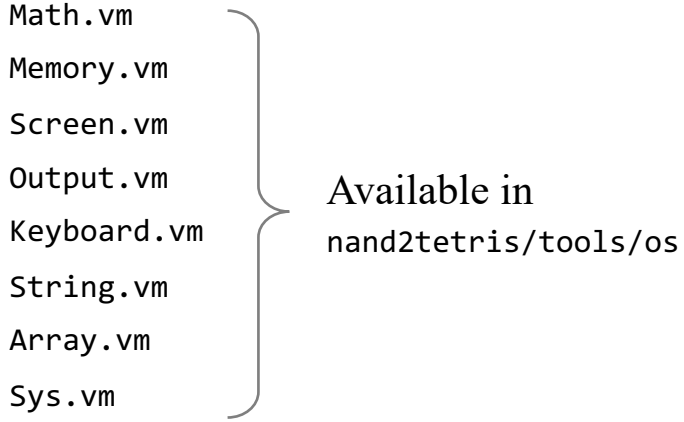
  Setting `pointer 0` to `alloc`'s return value
- The generated VM code ends with `return pointer 0`

When compiling a *void* function or a *void* method:

The generated VM code ends with `push constant 0` and then `return`

The OS (implementation notes)

- The OS is written in Jack (later in the course)
- Implemented as a set of 8 compiled Jack classes:



- Every OS subroutine *ClassName*`.`*subName* is available as a compiled VM function, and can be called by the generated VM code using the usual call command `call` *ClassName*`.`*subName* *nArgs*

Usage

If you execute / test the generated VM code on the supplied VM emulator (recommended in this project), then there is no need to include or translate the OS files: The supplied VM emulator features a built-in implementation of all the OS subroutines.

If you wish to translate the generated VM code to assembly, copy all the `nand2tetris/tools/os/*.vm` files into same folder as the VM files generated by the compiler, and apply the translator to the folder.

The OS (implementation notes)

Some OS routines come to play during compilation. In particular:

The compiler handles…

Multiplication (*) by calling the OS function `Math.multiply()`

Division (/) by calling the OS function `Math.divide()`

String constants by calling the OS constructor `String.new(`*length*`)`

String assignments like `x = "`*cc ... c*`"` by making a sequence of calls to `String.appendChar(`*c*`)`

Object construction by calling the OS function `Memory.alloc(`*size*`)`

Note: The compiler generates VM code, and the OS routines are implemented as VM functions.
So, every call above is implemented using the regular VM command `call` *OSfunction nArgs*

Lecture plan

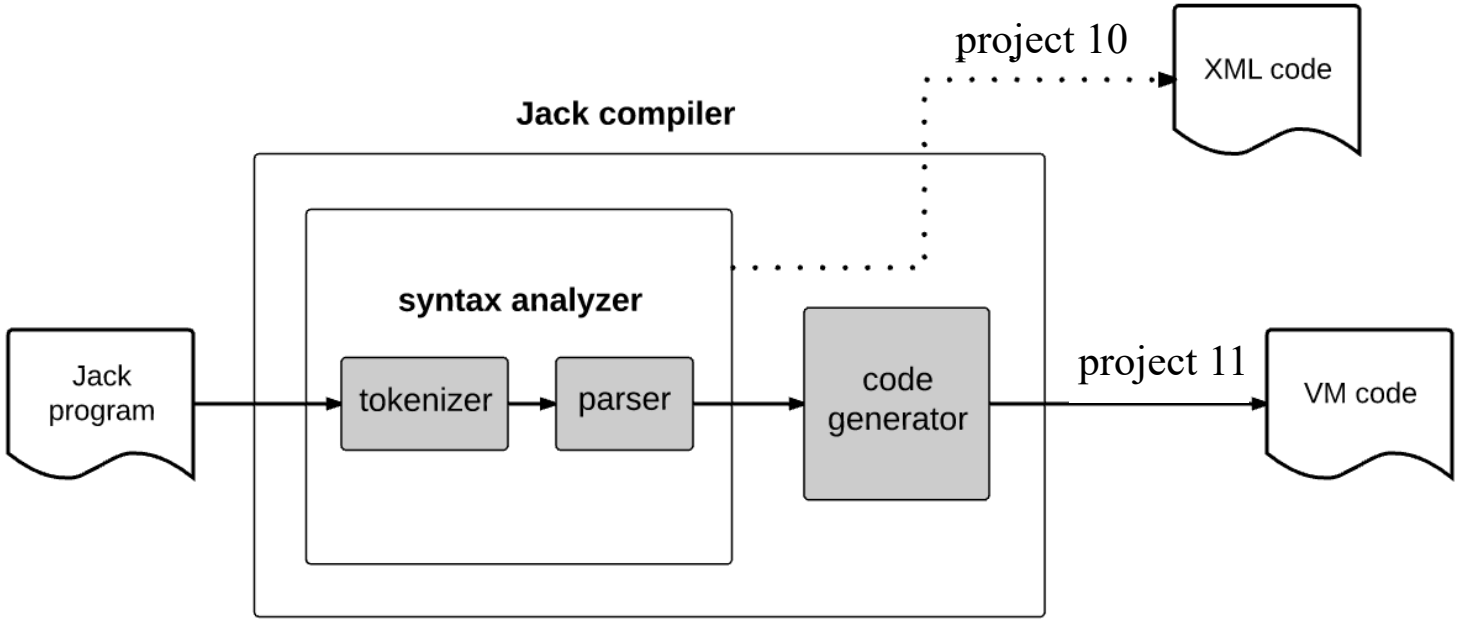
Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- ✓ Handling objects
- ✓ Handling arrays

Implementation

- ✓ Standard mapping
- ➡ Proposed design
- Project 11

The Jack compiler



Project 11: Morphing the syntax analyzer into a full scale compiler, using:

- `JackCompiler`: top-most ("main") module
- `JackTokenizer`
- `CompilationEngine`
- `SymbolTable`
- `VMWriter`

The Jack compiler

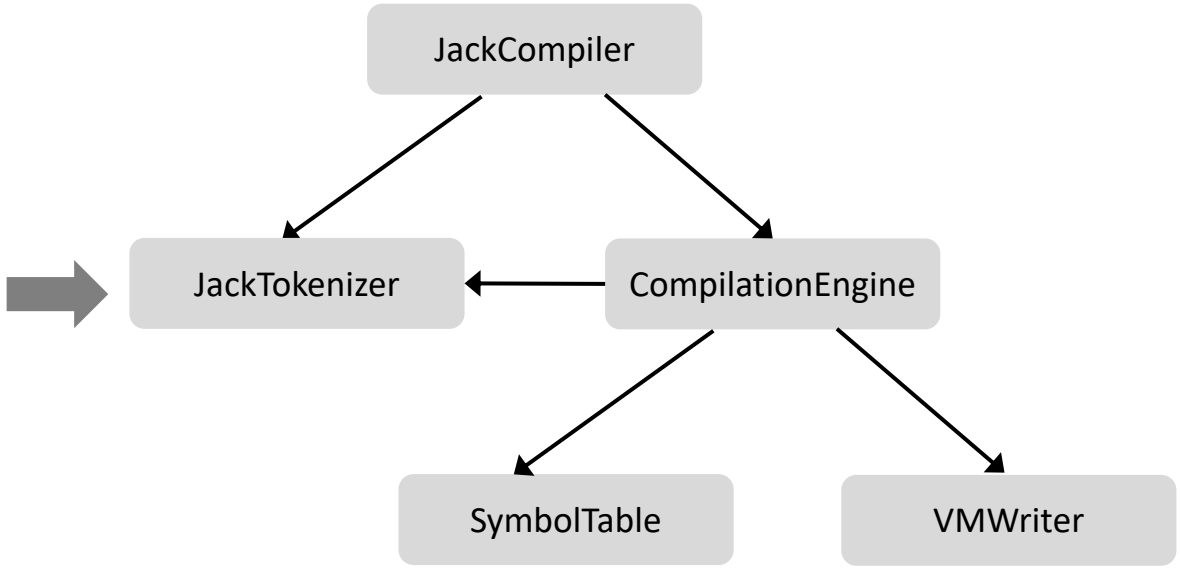
Usage

```
$ JackCompiler input
```

input: *fileName*`.jack`: name of a single file containing a Jack class, or
folderName: name of a folder containing one or more `.jack` files

output: If the input is a single file: *fileName*`.vm`
If the input is a folder: One `.vm` file for every `.jack` file, stored in that folder

The Jack compiler



- For each source `.jack` file, the compiler creates a `JackTokenizer` and an output `.vm` file
- Next, the compiler uses the `CompilationEngine` to write the VM code into the output `.vm` file.

JackTokenizer

The `JackTokenizer` handles the compiler's input.

Provides services for:

- Skipping white space
- Getting the current token and advancing the input just beyond it
- Getting the type of the current token

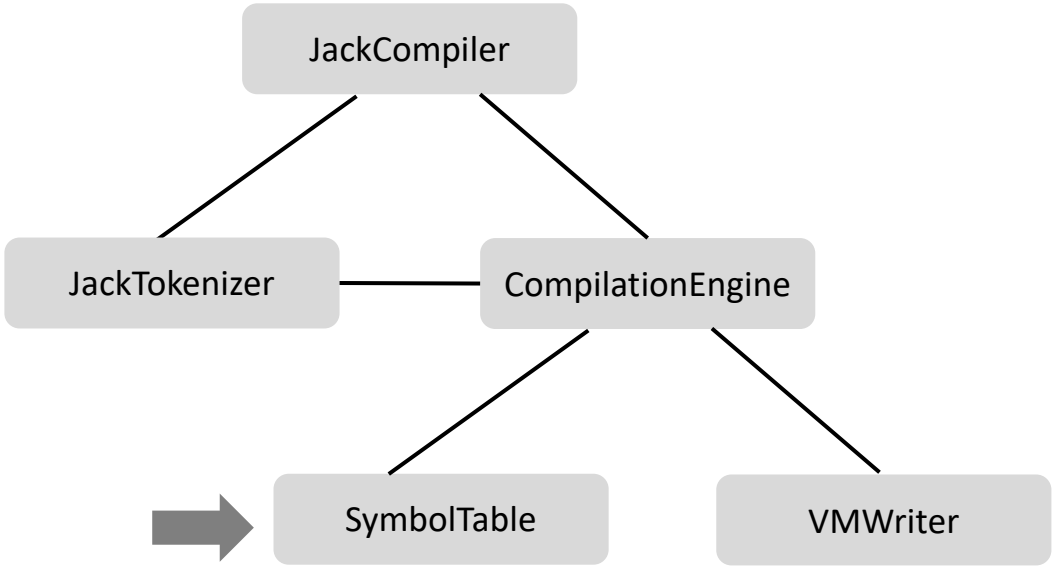
(Developed in project 10)

JackTokenizer (same as in project 10)

JackTokeinizer: Ignores all comments and white space, gets the next token, and advances the input just beyond it

Routine	*Arguments*	*Returns*	*Function*
Constructor / initializer	input file / stream	–	Opens the input `.jack` file / stream and gets ready to tokenize it.
`hasMoreTokens`	–	boolean	Are there more tokens in the input?
`advance`	–	–	Gets the next token from the input, and makes it the current token. This method should be called only if `hasMoreTokens` is true. Initially there is no current token.
`tokenType`	–	`KEYWORD`, `SYMBOL`, `IDENTIFIER`, `INT_CONST`, `STRING_CONST`	Returns the type of the current token, as a constant.
`keyWord`	–	`CLASS`, `METHOD`, `FUNCTION`, `CONSTRUCTOR`, `INT`, `BOOLEAN`, `CHAR`, `VOID`, `VAR`, `STATIC`, `FIELD`, `LET`, `DO`, `IF`, `ELSE`, `WHILE`, `RETURN`, `TRUE`, `FALSE`, `NULL`, `THIS`	Returns the keyword which is the current token, as a constant. This method should be called only if `tokenType` is `KEYWORD`.
`symbol`	–	char	Returns the character which is the current token. Should be called only if `tokenType` is `SYMBOL`.
`identifier`	–	string	Returns the string which is the current token. Should be called only if `tokenType` is `IDENTIFIER`.
`intVal`	–	int	Returns the integer value of the current token. Should be called only if `tokenType` is `INT_CONST`.
`stringVal`	–	string	Returns the string value of the current token, without the opening and closing double quotes. Should be called only if `tokenType` is `STRING_CONST`.

The Jack compiler



SymbolTable

Jack source code

```
class Point {
   field int x, y;
   static int pointCount;
   ...
   method int distance(Point other) {
      var int dx, dy;
      let dx = x - other.getx();
      let dy = y - other.gety();
      return Math.sqrt((dx*dx)+ (dy*dy));
    }
    ...
}
```

name	type	kind	#
x	int	field	0
y	int	field	1
pointCount	int	static	0

class-level symbol table

name	type	kind	#
this	Point	argument	0
other	Point	argument	1
dx	int	local	0
dy	int	local	1

subroutine-level symbol table

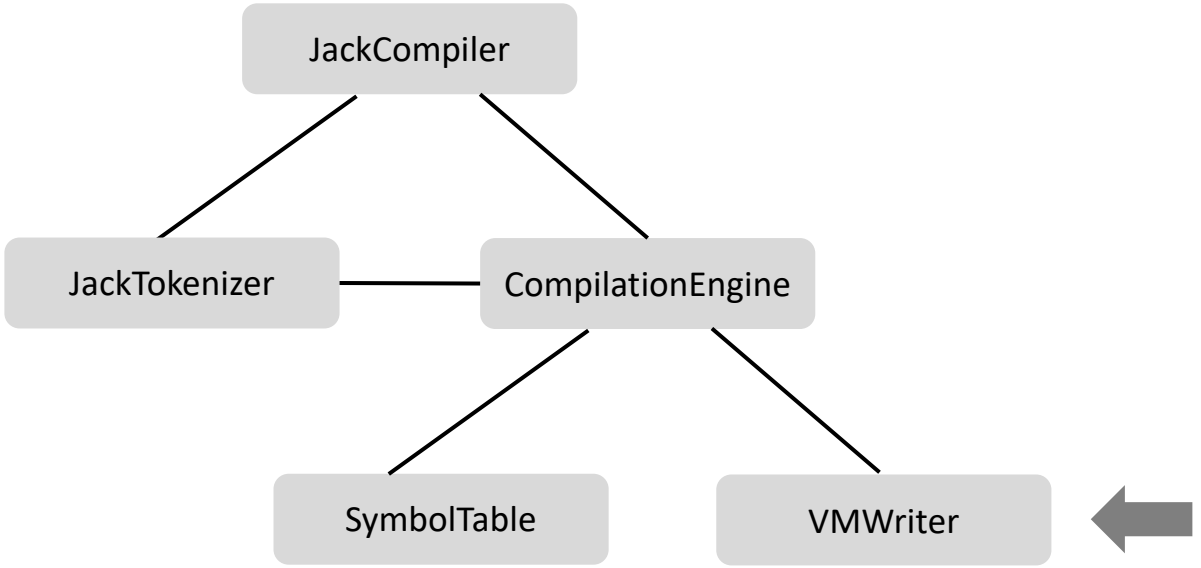
Implementation notes

- symbol table = instance of a `SymbolTable` class (next slide)
- When compiling a Jack class, we need one class-level symbol table and one subroutine-level symbol table
- When we start compiling a subroutine, we reset the latter table
- Each variable is assigned a running index within its *scope* (table) and *kind*. The index starts at 0, increments by 1 after each time a new symbol is added to the table, and is reset to 0 when starting a new scope (table)
- When compiling an error-free Jack code, each identifier not found in the symbol tables can be assumed to be either a *subroutine name* or a *class name*.

SymbolTable

Routine	*Arguments*	*Returns*	*Function*
Constructor / initializer	—	—	Creates a new symbol table.
`reset`	—	—	Empties the symbol table, and resets the four indexes to 0. Should be called when starting to compile a subroutine declaration.
`define`	`name` (string) `type` (string) `kind` (`STATIC`, `FIELD`, `ARG`, or `VAR`)	—	Defines (adds to the table) a new variable of the given `name`, `type`, and `kind`. Assigns to it the index value of that `kind`, and adds 1 to the index.
`varCount`	`kind` (`STATIC`, `FIELD`, `ARG`, or `VAR`)	int	Returns the number of variables of the given `kind` already defined in the table.
`kindOf`	`name` (string)	(`STATIC`, `FIELD`, `ARG`, `VAR`, `NONE`)	Returns the `kind` of the named identifier. If the identifier is not found, returns `NONE`.
`typeOf`	`name` (string)	string	Returns the `type` of the named variable.
`indexOf`	`name` (string)	int	Returns the `index` of the named variable.

The Jack compiler

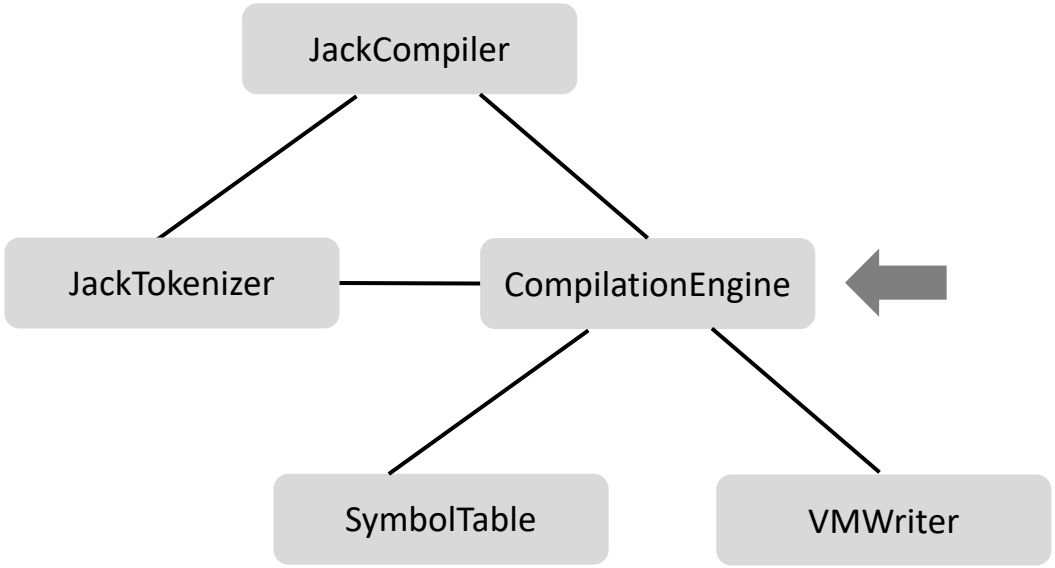


VMWriter

Routine	*Arguments*	*Returns*	*Function*
Constructor / initializer	output file / stream	—	Creates a new output `.vm` file / stream, and prepares it for writing.
`writePush`	`segment` (`CONSTANT`, `ARGUMENT`, `LOCAL`, `STATIC`, `THIS`, `THAT`, `POINTER`, `TEMP`) `index` (int)	—	Writes a VM `push` command.
`writePop`	`segment` (`ARGUMENT`, `LOCAL`, `STATIC`, `THIS`, `THAT`, `POINTER`, `TEMP`) `index` (int)	—	Writes a VM `pop` command.
`writeArithmetic`	`command` (`ADD`, `SUB`, `NEG`, `EQ`, `GT`, `LT`, `AND`, `OR`, `NOT`)	—	Writes a VM arithmetic-logical command.
`writeLabel`	`label` (string)	—	Writes a VM `label` command.
`writeGoto`	`label` (string)	—	Writes a VM `goto` command.
`writeIf`	`label` (string)		Writes a VM `if-goto` command.
`writeCall`	`name` (string) `nArgs` (int)	—	Writes a VM `call` command.
`writeFunction`	`name` (string) `nVars` (int)	—	Writes a VM `function` command.
`writeReturn`	—	—	Writes a VM `return` command.
`close`	—	—	Closes the output file / stream.

A simple module that writes individual VM commands to the output `.vm` file.

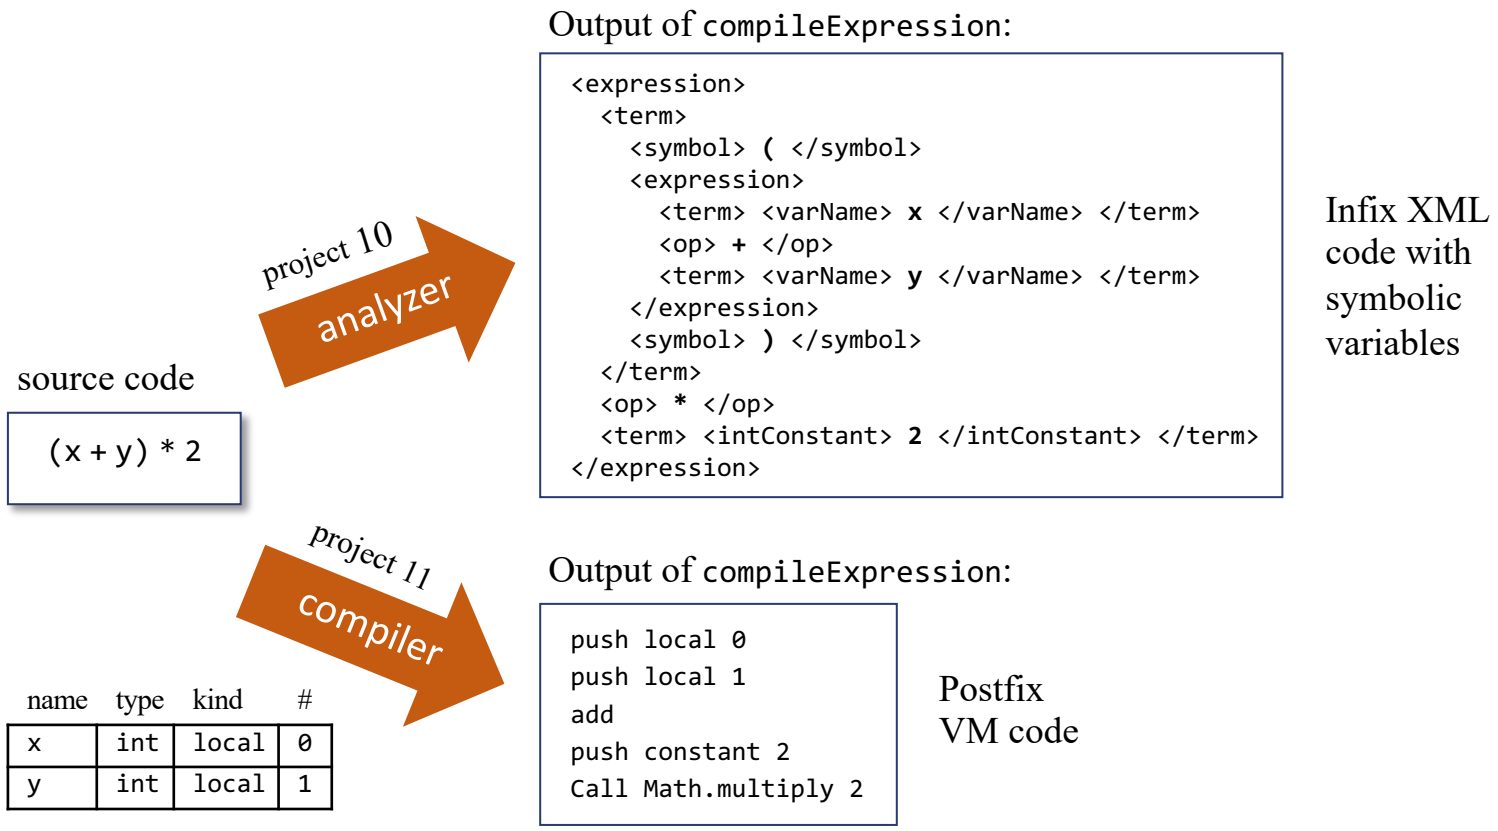
The Jack compiler



CompilationEngine

The `CompilationEngine` of the *compiler* (project 11) and the *syntax analyzer* (project 10) have the same design and API: a set of `compile`*xxx* methods

However, the `compile`*xxx* methods generate different outputs. For example:



CompilationEngine

- Gets its input from a `JackTokenizer` and writes its output using the `VMWriter`
- Organized as a set of `compile`*xxx* routines, *xxx* being a syntactic element in the Jack grammar:
  - Each `compile`*xxx* routine should read *xxx* from the input, `advance()` the input exactly beyond *xxx*, and emit to the output VM code effecting the semantics of *xxx*
  - `compile`*xxx* is called only if *xxx* is the current syntactic element
  - If *xxx* is part of an expression and thus has a value, the emitted VM code computes the value and leaves it at the top of the VM's stack

CompilationEngine (same API as in project 10)

Routine	*Arguments*	*Returns*	*Function*
Constructor / initializer	Input file / stream Output file / stream		Creates a new compilation engine with the given input and output. The next routine called must be `compileClass`.
`compileClass`	–	–	Compiles a complete class.
`compileClassVarDec`	–	–	Compiles a static variable declaration, or a field declaration.
`compileSubroutine`	–	–	Compiles a complete method, function, or constructor.
`compileParameterList`	–	–	Compiles a (possibly empty) parameter list. Does not handle the enclosing parentheses tokens `(` and `)`.
`compileSubroutineBody`	–	–	Compiles a subroutine's body.
`compileVarDec`	–	–	Compiles a `var` declaration.
`compileStatements`	–	–	Compiles a sequence of statements. Does not handle the enclosing curly bracket tokens `{` and `}`.

CompilationEngine (same API as in project 10)

Routine	*Arguments*	*Returns*	*Function*
`compileLet`	–	–	Compiles a `let` statement.
`compileIf`	–	–	Compiles an `if` statement, possibly with a trailing `else` clause.
`compileWhile`	–	–	Compiles a `while` statement.
`compileDo`	–	–	Compiles a `do` statement.
`compileReturn`	–	–	Compiles a `return` statement.
`compileExpression`	–	–	Compiles an expression.
`compileTerm`	–	–	Compiles a *term*. If the current token is an *identifier*, the routine must resolve it into a *variable*, an *array entry*, or a *subroutine call*. A single lookahead token, which may be `[`, `(`, or `.`, suffices to distinguish between the possibilities. Any other token is not part of this term and should not be advanced over.
`compileExpressionList`	–	int	Compiles a (possibly empty) comma-separated list of expressions. Returns the number of expressions in the list.

Lecture plan

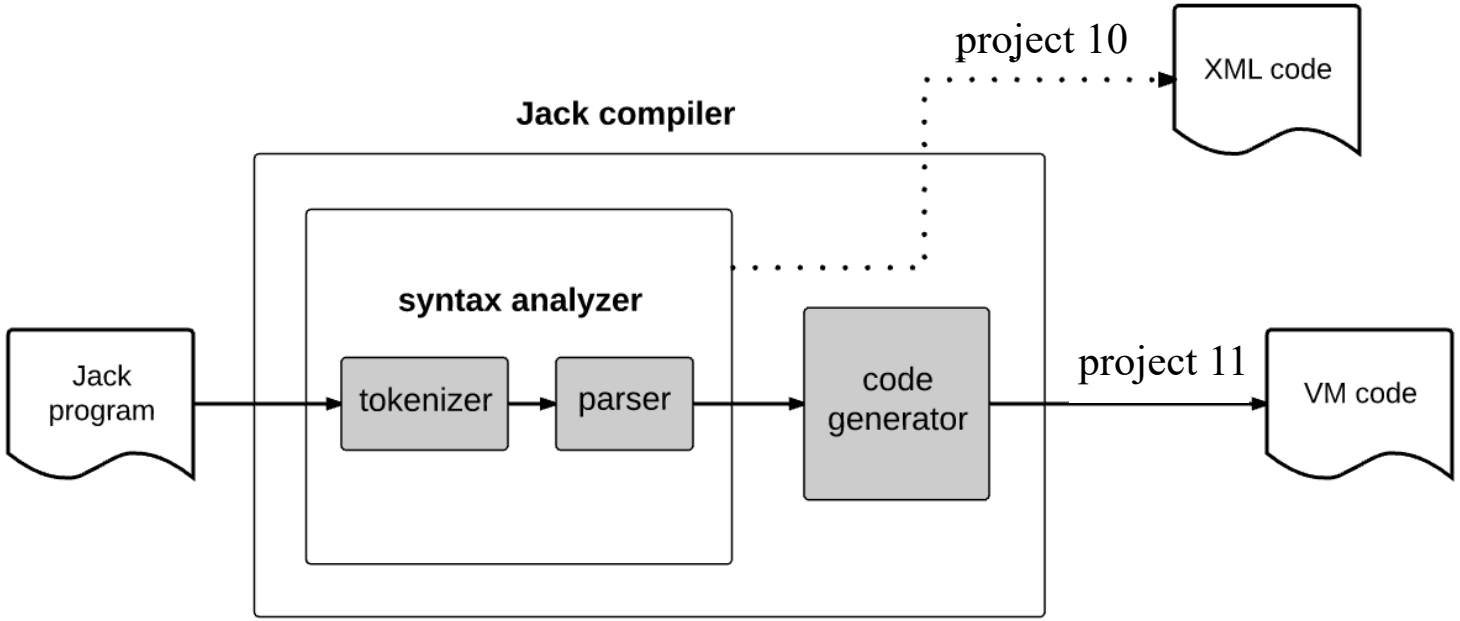
Compilation

- ✓ Handling variables
- ✓ Handling expressions
- ✓ Handling statements
- ✓ Handling objects
- ✓ Handling arrays

Implementation

- ✓ Standard mapping
- ✓ Proposed design
- ➡ Project 11

Compiler development roadmap



Project 11: Extend the syntax analyzer into a full-scale compiler

Stage 0: Syntax analyzer (done)

Stage 1: Symbol table handling

Stage 2: Code generation.

Symbol table

Output of the syntax analyzer (project 10)

```
...
<expression>
    <term>
        <identifier> count </identifier>
    </term>
    <symbol> < </symbol>
    <term>
        <intConstant> 100 </intConstant>
    </term>
</expression>
...
```

In the syntax analyzer built in project 10, identifiers were handled by outputting `<identifier>` *identifier* `</identifier>`

Extend the handling of identifiers:

- Output the identifier's category: `var`, `argument`, `static`, `field`, `class`, `subroutine`
- If the identifier's category is `var`, `argument`, `static`, `field`,
  output also the running index assigned to this variable in the symbol table
- Output whether the identifier is being defined, or being used

Implementation

1. Implement the `SymbolTable` API
2. Extend the syntax analyzer developed in project 10 with the outputs described above (plan and use your own output/tags format)
3. Test the extended syntax analyzer by running it on the test programs given in project 10.

Compiler development roadmap

Project 11: Extend the syntax analyzer into a full-scale compiler

- ✓ Stage 0: Syntax analyzer (done)
- ✓ Stage 1: Symbol table handling
- ➡ Stage 2: Code generation.

Code generation

Test programs

- `Seven`
- `ConvertToBin`
- `Square`
- `Average`
- `Pong`
- `ComplexArrays`

Test your evolving compiler on the supplied test programs, in the shown order

Each test program is designed to test some of your compiler's capabilities.

For each test program:

1. Use your compiler to compile the program folder
2. Inspect the generated code;
   If there's a problem, fix your compiler and go to stage 1
3. Load the folder into the VM emulator
4. Run the compiled program, inspect the results
5. If there's a problem, fix your compiler and go to stage 1.

Test program: Seven

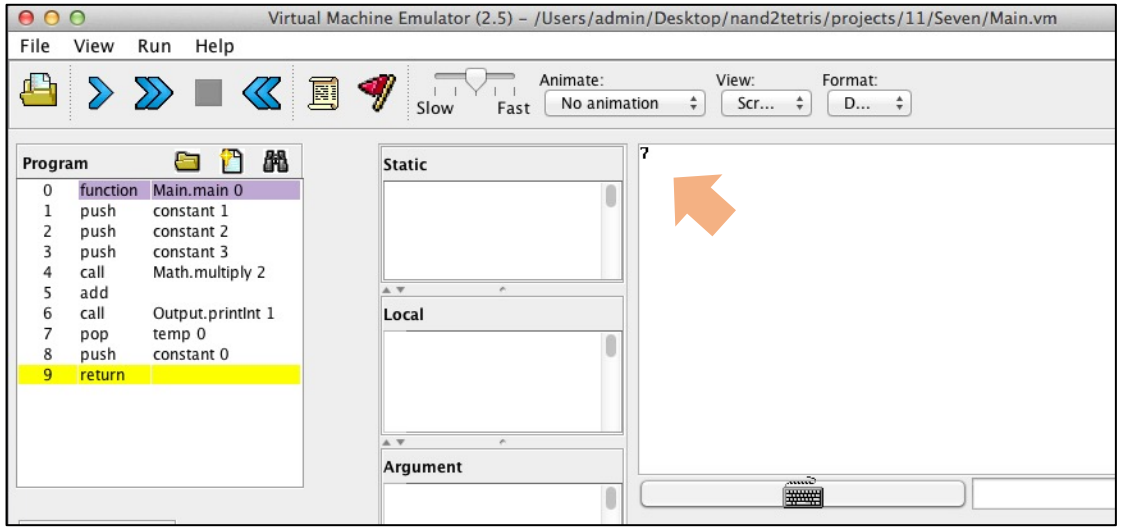
projects/11/Seven/Main.jack

```
/** Computes the value of 1 + (2 * 3)
 * and prints the result at the top-left
 * corner of the screen. */
class Main {
   function void main() {
       do Output.printInt(1 + (2 * 3));
       return;
   }
}
```

JackCompiler

projects/11/Seven/Main.vm

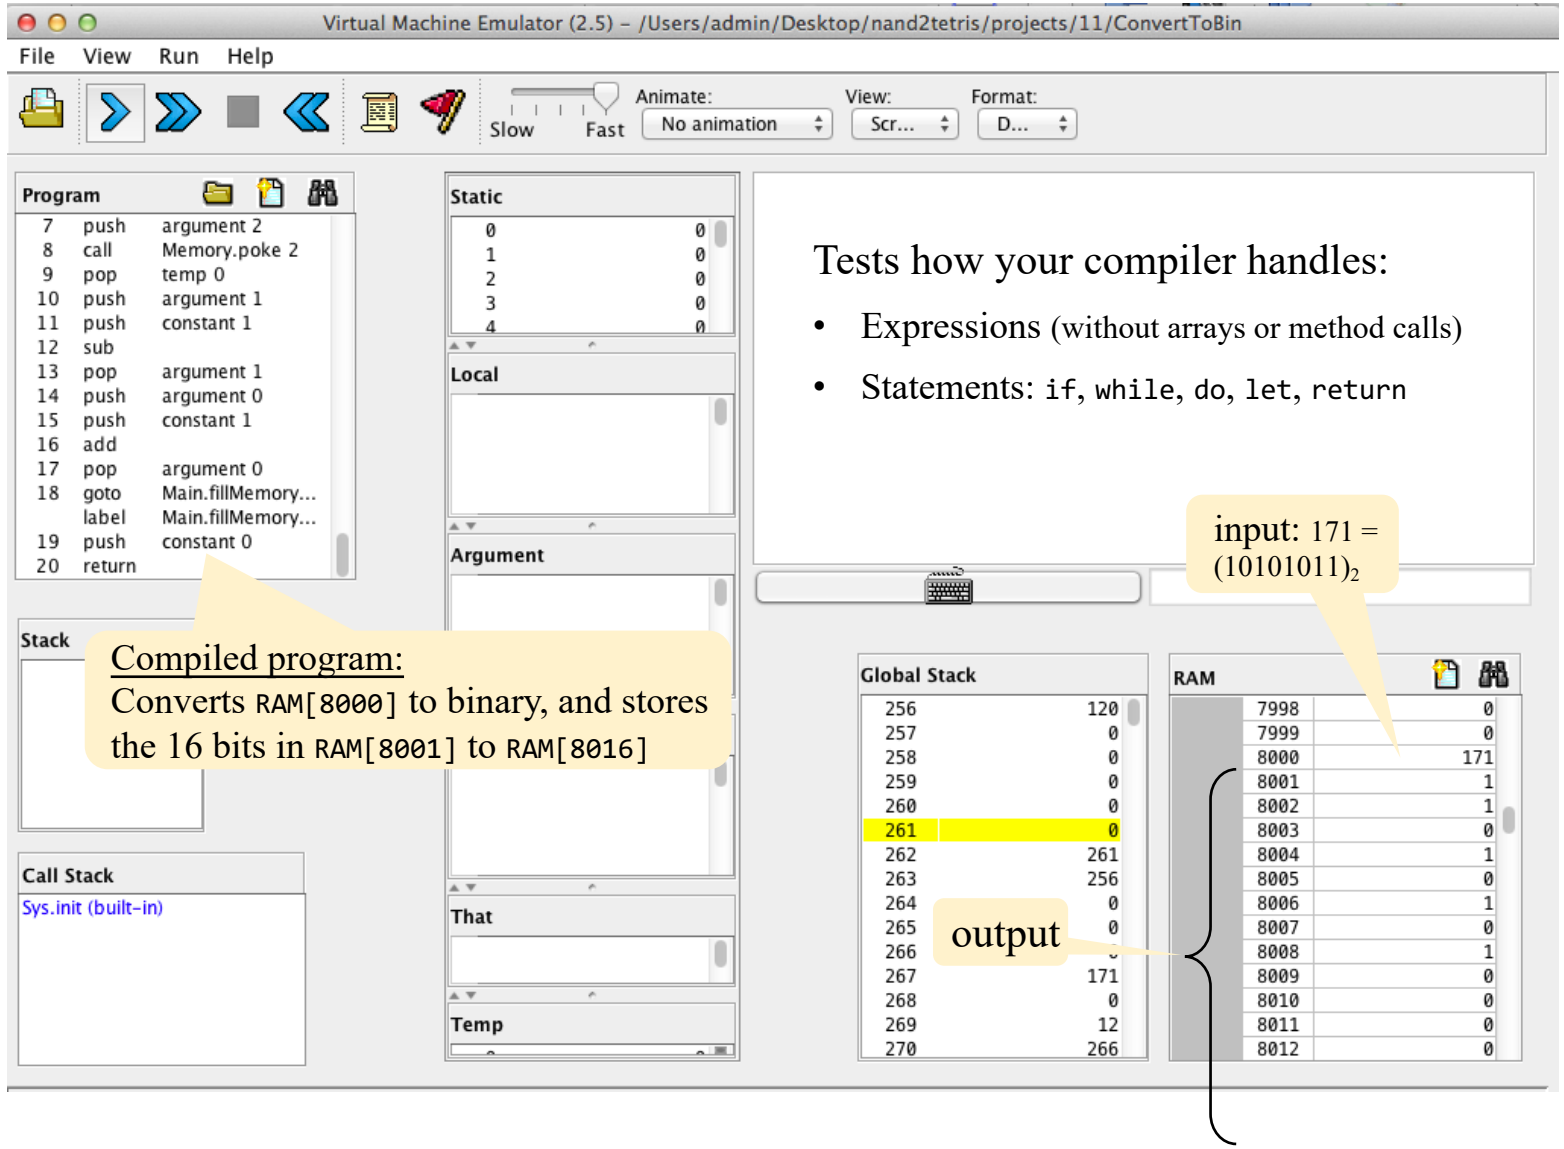
```
function Main.main 0
  push constant 1
  push constant 2
  push constant 3
  call Math.multiply 2
  add
  call Output.printInt 1
  pop temp 0
  push constant 0
  return
```



Tests how your compiler handles:

- A simple program
- An arithmetic expression involving constants only
- A `do` statement
- A `return` statement

Test program: Decimal-to-binary conversion



Test program: Decimal-to-binary conversion

```
class Main {
   // Converts RAM[8000] to binary, putting the resulting bits in RAM[8001]..RAM[8016]
   function void main() {
      var int value;
      do Main.fillMemory(8001, 16, -1);  // sets RAM[8001]..RAM[8016] to -1
      let value = Memory.peek(8000);     // gets the input from RAM[8000]
       do Main.convert(value);            // performs the conversion
      return;
   }

   // Fills 'length' consecutive memory locations with 'value',
   // starting at 'startAddress'.
   function void fillMemory(int startAddress, int length, int value) { // code omitted }

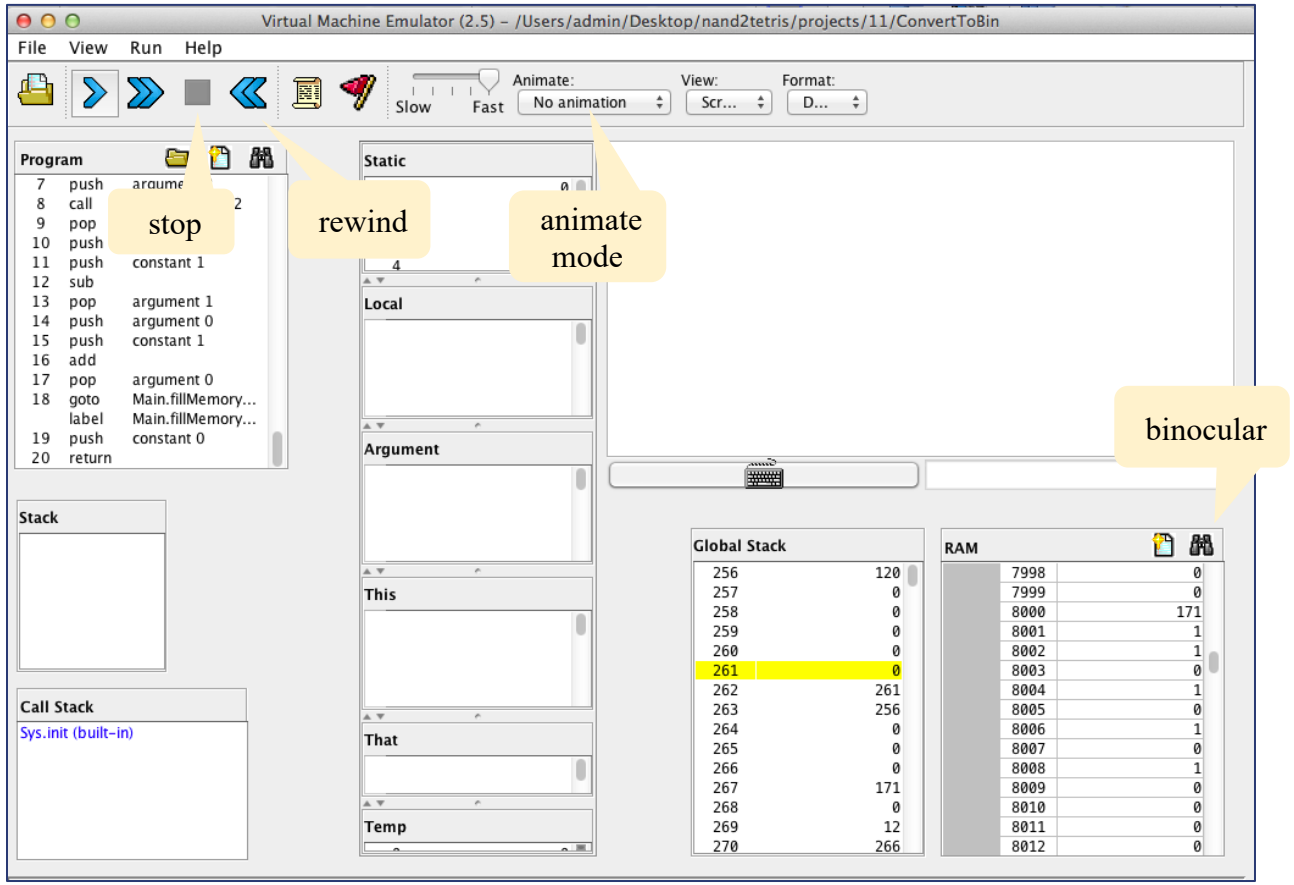
   // Converts the value to binary, and puts the result in RAM[8001]..RAM[8016] */
   function void convert(int value) { // code omitted }

   // Some more private functions (omitted)
}
```

Tests how your compiler handles:

- Expressions (without arrays, without method calls)
- Statements: `if`, `while`, `do`, `let`, `return`

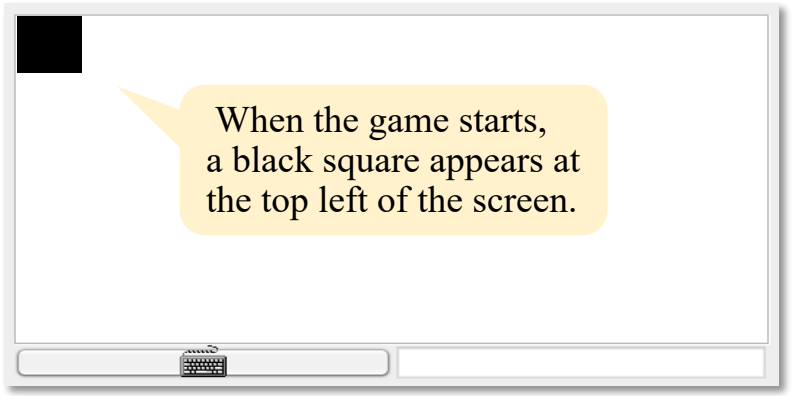
Test program: Decimal-to-binary conversion

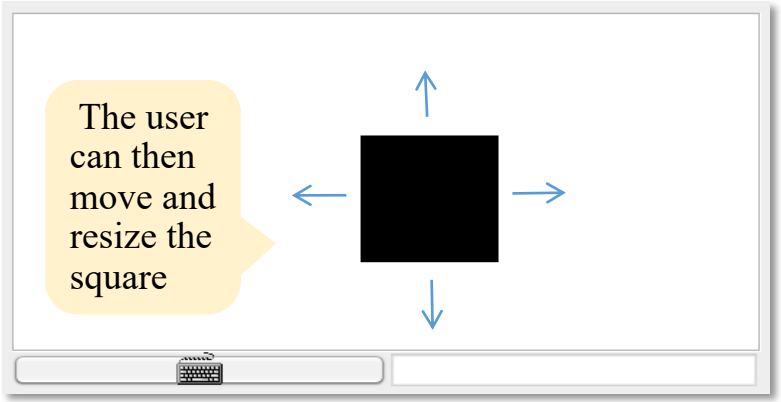


Testing tips:

- Use the "binocular" control
- Note that the "rewind" control erases the RAM
- Note that you cannot enter input into the RAM in "no animation" mode
- To see the program's results (RAM state), click the "stop" control

Test program: Square

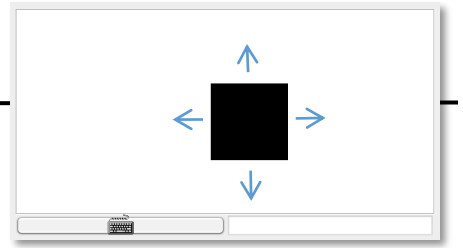




Tests how your compiler handles object-oriented features of the Jack language:

- Constructors
- Methods
- Expressions that include method calls.

Test program: Square



projects/11/Square/Square.jack (showing only method signatures)

```
/** Represents a graphical square object */
class Square {

   /** Constructs a new square with a given location and size */
   constructor Square new(int Ax, int Ay, int Asize)

   /** Disposes this square */
   method void dispose()

   /** Draws the square on the screen *
   method void draw()

   /** Erases the square from the scree
   method void erase()

   /** Increments the square's size by
   method void incSize()

   /** Decrements the square's size by
   method void decSize()

   /** Moves up by 2 pixels */
   method void moveUp()

   /** Moves down by 2 pixels */
   method void moveDown()

   /** Moves left by 2 pixels */
   method void moveLeft()

   /** Moves right by 2 pixels */
   method void moveRight()
}
```

SquareGame.jack

```
/** Represents a square game */
class SquareGame {

   field Square square; // the square
   field int direction; // the square's direction:
                        // 0=none, 1=up, 2=down,
                        // 3=left, 4=right

   /** Constructs a new Square Game */
   constructor SquareGame new() {
      let square = Square.new(0, 0, 30);
      let direction = 0;
      return this;
   }

   /** Disposes this game */
   method void dispose() {
      do square.dispose();
      do Memory.deAlloc(this);
      return;
   }

   ...
```

Main.jack

```
/** Main class of the square game. */
class Main {

   /** Initializes and starts a new game */
   function void main() {
      var SquareGame game;

      let game = SquareGame.new();
      do game.run();
       do game.dispose();
      return;
    }
}
```

Test program: Average

```
/** Computes the average of a sequence of integers */
class Main {
   function void main() {
      var Array a;
      var int length;
      var int i, sum;

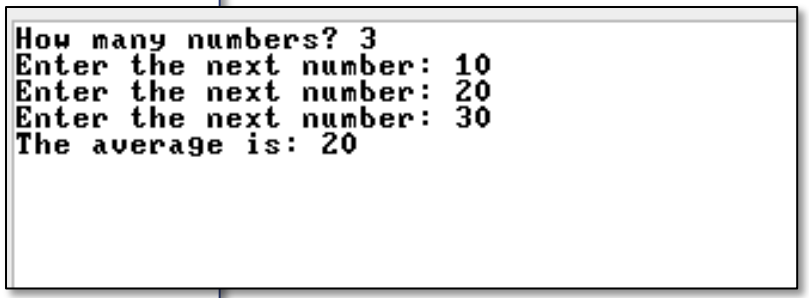
      let length = Keyboard.readInt("How many numbers? ");
      let a = Array.new(length);
      let i = 0;

      while (i < length) {
          let a[i] = Keyboard.readInt("Enter the next number: ");
          let i = i + 1;
      }

      let i = 0; let sum = 0;

       while (i < length) {
        let sum = sum + a[i];
         let i = i + 1;
       }

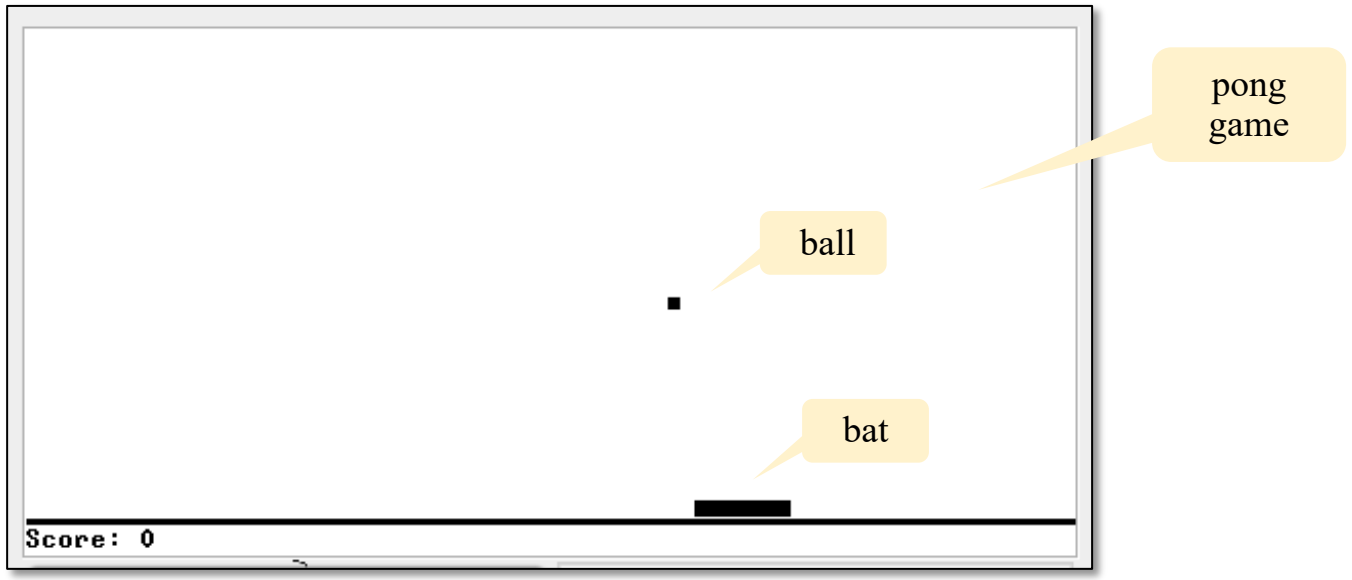
      do Output.printString("The average is: ");
      do Output.printInt(sum / length);
      do Output.println();
      return;
   }
}
```



Tests how your compiler handles:

- Arrays
- Strings

Test program: Pong



Tests how your compiler handles a complete object-oriented application, including the handling of objects and static variables.

Test program: Pong

projects/11/Pong/Ball.jack

```
/** A graphic ball, with methods for drawing, erasing
 * and moving on the screen. */
class Ball {

    // Ball'
    field in

    // Dista
    field in

    // Used
    field in
    field bo

    // Locat
    field in

    // last
    field in

    /** Cons
     *  loca
    construc

    ...

    // More

}
```

Bat.jack

```
/** A graphic paddle with methods for drawing,
 *  erasing, moving left and right changing width. */
class Bat {

    // Screen location
    field int x, y;

    // Bat's width and height
    field int width, height;

    // Bat's direction of mov
    field int direction; // 1

    /** Constructs a new bat
    constructor Bat new(int A
                        int A
        let x = Ax;
        let y = Ay;
        let width = Awidth;
        let height = Aheight;
        let direction = 2;
        do show();
        return this;
    }

    ...

    // More Bat methods

}
```

PongGame.jack

```
/** Pong game */
class PongGame {

   static PongGame instance;  // the game
   field Bat bat;             // the bat
   field Ball ball;           // the ball
   ...
   /** Creates an instance of a PongGame */
   function void newInstance() {
      let instance = PongGame.new();
      return;
    }
    ...
    /** Runs the g
    method void ru
       var char ke
       while (~exi
          // waits
          while ((
             let k
             do ba
             do mo
          }

          if (key
                dc
          }
          ...
       }
    }
    ...
}
```

Main.jack

```
/** Main class of the Pong game */
class Main {
   /** Initializes a Pong game and
   starts running it. */
   function void main() {
      var PongGame game;
      do PongGame.newInstance();
      let game = PongGame.getInstance();
      do game.run();
      do game.dispose();
      return;
   }
}
```

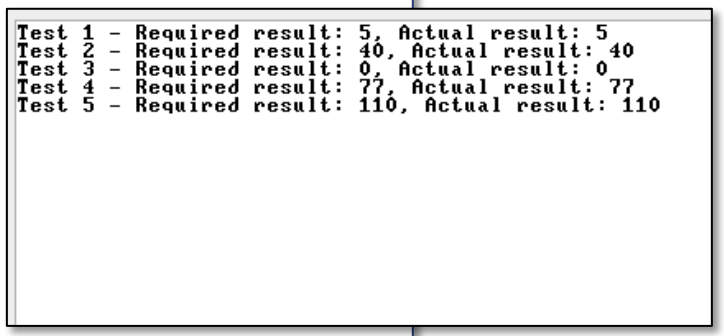
Test program: ComplexArrays

projects/11/ComlpexArrays/Main.jack

```
class Main {
   function void main() {
      var Array a, b, c;
      let a = Array.new(10);
      let b = Array.new(5);
      ...
      // Fills the arrays with some data (omitted)
      ...
      // Manipulates the arrays using some complex index expressions
      let a[b[a[3]]] = a[a[5]] * b[7 - a[3] - Main.double(2) + 1];
      ...
      // Prints the expected and the actual values of a[b[a[3]]]
      ...
   }

   // A trivial function that tests how the compiler handles a subroutine
   // call within an expression that evaluates to an array index
   function int double(int a) {
      return a * 2;
   }

   // Creates a two dimensional array
   function void fill(Array a, int size) {
      while (size > 0) {
         let size = size - 1;
         let a[size] = Array.new(3);
      }
      return;
   }
}
```



Tests how your compiler handles array manipulations using index expressions that include complex array references
